11 12 13	1. INTRODUCTION
14 15	Diagnostic tests are widely used in many areas. In particular, these tests have huge importance in medicine sector. By courtesy of early and accurate diagnosis, the morbidity

16 and mortality of disease can be reduced. For this reason, it is important to compare various diagnostics test with each other under specific clinical conditions in order to determine which

18 one is the best to use.

19 One of the approaches used to analyze the performance of diagnostic tests is ROC theory. 20 The roots of ROC theory are laid on statistical decision theory. ROC theory is related to 21 many fields. It was not only used in the 1950's for radio signals, but also used in the 2010's 22 for predictions of land changes, species distributions and ecological niches [1]. In particular, 23 the usage of ROC analysis was canalized to the medicine sector after 1960's. Since that 24 time, ROC played an essential role in medicine sector and it is still widely used in this sector. ROC curves became the standard approach to summarizing diagnostic test performance 25 after published a medical application of this method as [2]. 26

The other approach which is used to analyze the performance of diagnostic tests in recent 27 vears is information theory. Information theory was developed by Claude Shannon (1948). In 28 Shannon's theory,[3], the information is associated with uncertainty. This theory of 29 knowledge and uncertainty for the measurement is based on a mathematical basis. Metz, 30 Goodenough and Rossmann[4] developed a formula used in assessing the performance of 31 32 diagnostic tests by using information theory. After this work, Mossman and Somoza [5] 33 developed a new mathematical and graphical method to evaluate and compare the performance of diagnostic tests for the value of any prevalence by using the properties of the 34 35 ROC analysis and information theory approach. In [6] obtained the distance between 36 patients and healthy distributions by using the concept of relative entropy. Benish[7] investigated the concept of relative entropy with a different perspective. 37

38 In this study, the performance of the two diagnosis tests on the field of rheumatic disorder is analyzed by using receiver operating characteristic and fundamental concepts of information 39 theory. ASO values are used for the diagnosis of rheumatic disorder. ASO is a value which 40 is used to learn whether the patients have group "A" beta-hemolytic streptococcal infection 41 which causes these diseases. In this article, ASO values are measured by using 42 Turbidimetric tests which belong to two different firms. These tests were called as I. 43 Turbidimetric test and II. Turbidimetric test. The aims of this study to investigate which 44 45 Turbidimetric test has better performance and to demonstrate which test can be an 46 alternative to gold standard (Nefelometric test) test.

47

#### 48 2. MATERIAL AND METHODS

# 49 2.1.RECEIVER OPERATING CHARACTERISTIC(ROC) CURVE

50 The ROC curve is a fundamental tool for diagnostic test evaluation. When it is considered 51 the results of a particular test in two populations, one population with a disease, the other 52 population without the disease, it will be rarely observed a perfect separation between the 53 two groups. Indeed, the distribution of the test results will overlap, as shown in the following 54 Figure 1.

55

# 58 Fig.1. Two distributions of diseased and non-diseased group

59

For every possible cut-off point or criterion value (threshold value) is selected to discriminate between the two populations, there will be some cases with the disease correctly classified as positive (TP = True Positive fraction), but some cases with the disease will be classified negative (FN = False Negative fraction). On the other hand, some cases without the disease will be correctly classified as negative (TN = True Negative fraction), but some cases without the disease will be classified as positive (FP = False Positive fraction). The different fractions (TP, FP, TN, FN) are represented in Table 1 [8].

67

#### 68Table 1.Different fractions(TP, FP, TN, FN)

Test	Truth		
Results	Positive	Negative	
Positive	TP	FP	
Negative	FN	TN	

69

There are some criteria to measure the performance of the diagnostic test. Sensitivity, specificity and efficiency (accuracy) are some of the performance criteria. These criteria are based on the Table 1. Sensitivity is a probability that a test result will be positive when the disease is present. It is equal to TP fraction. Specificity is a probability that a test result will be negative when the disease is not present. It is equal to one minus FP fraction. Efficiency is calculated by total number of TP and FP over sample size. It gives a clue about the accuracy of the diagnostic test.

In a receiver operating characteristic (ROC) curve the true positive fraction (TP or 77 78 sensitivity) is plotted in function of the false positive fraction (FP or 1- specificity) for different 79 cut-off points. Each point on the ROC curve represents sensitivity and one minus specificity pair corresponding to a particular decision threshold. FP fraction amounts to costs and TP 80 81 fraction amounts to benefits. A test with perfect discrimination (no overlap in the two 82 distributions) has a ROC curve that passes through the upper left (northwest) corner (100% sensitivity, 100% specificity). Therefore the closer the ROC curve is to the upper left 83 84 (northwest) corner, the higher the overall accuracy of the test [9]. The most commonly used global index of diagnostic accuracy is the area under the ROC curve (AUC) [10]. The total 85 86 area under the curve(AUC) is a measure of the performance of the diagnostic test since it 87 reflects the test performance at several possible cut-off levels. The area lies in the interval 88 [0,1] and the larger area, the better performance.

# 89 2.2.BASIC CONCEPTS OF INFORMATON THEORY

90 The performance of a diagnostic test is frequently described in terms of the amount of 91 information it provides. A fundamental concept of information theory, entropy and mutual 92 information, is directly applicable to evaluation of diagnostic test performance. In this section 93 we introduce most of the basic definitions in information theory required for evaluation of 94 diagnostic test performance[9].

The entropy of a random variable is a measure of the uncertainty of the random variable. It is the number of bits on average required to describe the random variable. Let *X* be a discrete random variable, taking a finite number of possible values  $X_1, X_2, ..., X_n$  with respective probabilities  $p_i \ge 0$  for i = 1, ..., n and  $\sum p_i = 1$ . The Shannon entropy H(X) is defined by [11].

102

104

$$H(X) = -\sum_{x} p(x) \log_2 p(x) \tag{1}$$

103 If 
$$(X, Y) \sim p(x, y)$$
, the conditional entropy  $H(X \setminus Y)$  is defined as

$$H(X \setminus Y) = -\sum_{x,y} p(x,y) \log_2 \frac{p(x,y)}{p(y)}$$
<sup>(2)</sup>

105 106

107

Mutual information is a measure of the distance between two probability distributions. The mutual information of two random variables is a quantity that measures the mutual dependence of the two variables. The interpretation is that when mutual information is absent, marginal distributions are independent and their entropies add up to total entropy. The mutual information I(X; Y) is the reduction in the uncertainty of X due to the knowledge of Y. I(X; Y) is calculated by the formula given below

115 
$$I(X;Y) = H(X) - H(X \setminus Y)$$
(3)  
116

# 117 2.3.INFORMATION-BASED MEASURES OF DIAGNOSTIC TEST 118 PERFORMANCE

119 The performance of a diagnostic test is identified with respect to amount of the reduction 120 of disease's uncertainty. The purpose of this section is to demonstrate how basic concepts in 121 information theory apply to the problem of quantifying diagnostic test performance.

While evaluating the performance of the diagnosis test using the information theory, we need to explain the concepts of test results and disease statement. Disease statement is denoted by *D*. On the condition that there are two statements such as the existence or the nonexistence of a disease, we can specify the disease statement as follows,

126

$$D = \{Di\}$$
  $i: \{+, -\}$ 

127 D + = Get ill before diagnosis test

128 D-= Get no ill before diagnosis test

129 T += Positive test results

130  $T \rightarrow =$  Negative test results

131 The probability distribution of the disease statement before the test is defined with P(D+)132 and P(D-) values. In this case, the entropy before the test is calculated as below.

133 134

135

$$H(D) = P(D+)log_2P(D+) + P(D-)log_2P(D-)$$
(4)

After the diagnosis test is applied, the uncertainty of the disease statement changes. On the
condition that the diagnosis test results are known, the entropy of the disease statement is
called conditional entropy and is calculated according to the formula below.

 $H(D \setminus T) = P(T+)[P(D+ \setminus T+)log_2P(D+ \setminus T+) + P(D- \setminus T+)log_2P(D- \setminus T+)] + P(T-)[P(D+ \setminus T-)log_2P(D+ \setminus T-) + P(D- \setminus T-)log_2P(D- \setminus T-)]$ (5)

140 141

142 If H(D) is defined as pretest entropy, we need to define  $H(D\setminus T)$  as the expected value of 143 posttest entropy [8,11]. Besides, the difference between H(D) and  $H(D\setminus T)$  is called as 144 mutual information and it is denoted by I(D;T). Mutual information is the reduction in the 145 uncertainty of *D* due to the knowledge of *T*. It is the general criterion of what the diagnosis 146 test will tell us. I(D;T)isdefined as

147

$$I(D;T) = H(D) - H(D \setminus T)$$

# 150 **2.4.APPLICATION**

151

Turbidimetric test and Nefelometric test are used for the diagnosis of rheumatic disorder. Both tests are based on the principal of impurity in the blood. Nefelometric test is accepted as the gold standard in the analysis of plasma protein with micro molecule of which molecule massiveness is measured with milligram. If Nefelometric test results are in the range of 0-200 IU/ml reference interval, the diagnosis is resulted as healthy for the person. If Nefelometric test results are over [0, 200] IU/ml reference interval, the diagnosis is resulted as ill for the person [12].

159

160 New Turbidimetric tests are alternatives to Nefelometric test and they are becoming more precise day by day for the specific proteins such as ASO, which is used for the diagnosis of 161 162 rheumatic disorder [12]. Furthermore, while the unit cost of the Nefelometric test is more 163 than the unit cost of the Turbidimetric test, there are disadvantages to the Nefelometric test such as the requirement of more space in the laboratory, occupying additional personnel and 164 165 orientation of them. There are no practical differences between those two tests with regard 166 to the duration of test results. Each laboratory is required to decide to work with whether 167 Turbidimetric test and Nefelometric test due to its substructure, patient potential and 168 establishment requirement.

169

170 In this study, ASO values being the first phase of the diagnosis of rheumatic disorder are 171 measured by using Turbidimetric tests which belong to two different firms. These tests were 172 called as I.Turbidimetric test and II.Turbidimetric test. The aims of this study to investigate 173 which Turbidimetric test has better performance and to demonstrate which test can be an 174 alternative to Nefelometric test.

- 175
- 176

# 177 **3. RESULTS AND DISCUSSION**

Diagnosis values, I. Turbidimetric test results and II. Turbidimetric test results are coded as
vectors in R programme. After coding process, ROC curves of the both tests are generated
in the Figure 2.

181 182

183

184

185

(6)

In Figure 2, it is observed that I. Turbidimetric test dominates II. Turbidimetric test for all
 sensitivity and specificity values. According to these results, AUC is calculated 0.98 for I.
 Turbidimetric test and 0.90 for II. Turbidimetric test.

The sensitivity(SE), specifity(SP) and efficiency(Eff) of both test for different threshold values are given in Table 2. Using sensitivity results, the threshold values 165 and 48 are chosen for I.Turbidimetric and II. Turbidimetric test respectively. Probabilities of detecting actually ill people on these threshold values are the greatest among all threshold values.

193

# 194Table 2. The sensitivity(SE), specifity(SP) and efficiency(Eff) of both test for different195threshold values

Test	Threshold V.	Sensitivity	Specificity	Efficiency
	165	0.96	0.90	0.91
I.Turbidimetric				
	173	0.92	0.97	0.95
	197	0.77	0.97	0.89
	48	0.96	0.41	0.63
II.Turbidimetric				
	101	0.92	0.78	0.83
	202	0.51	1.00	0.80

196

According to the specificity(SP) results in Table 2, the threshold values 173 and 202 are chosen for I.Turbidimetric and II. Turbidimetric test respectively. Probabilities of detecting actually healthy people on these threshold values are the greatest among all threshold values. Using the efficiency value(Eff) in Table.2, 173 is chosen the largest percent correct value which maximizes efficiency.

Diagnostic performance is measured in units of information for I. Turbidimetric and
 II. Turbidimetric test. Entropy, conditional entropy and mutual information values of both test
 are given in Table 3.

- 205
- 206
- 207 208

209

210

#### Table3. Entropy, conditional entropy and mutual information of two tests

Tests	H(D)	$H(D \setminus T)$	I(D;T)
I. Turbidimetric	0.96	0.50	0.46
II. Turbidimetric	0.96	0.63	0.33

212

213 On account of information theory analysis; if the disease statement is taken as the random 214 variable, the random variable is indicated either as the presence or the absence of the 215 disease before the diagnostic test. Under this circumstance the entropy of the disease is 216 only affected with the possibility of disease existence or disease non existence. Since these 217 possibilities are equal in both tests, the entropy of the disease is the same. In Table 3, the 218 entropy value is the same but mutual information values are different. According to the result of mutual information, I. Turbidimetric test provides more diagnostic information than II. 219 220 Turbidimetric test. Therefore I. Turbidimetric test dominates II. Turbidimetric test. Based on 221 these results, it can be verified that mutual information value is parallel to AUC value.

222 Another result of information theory analysis is the measurement of mutual information 223 values for all threshold values. While mutual information can be measured for all threshold 224 values. AUC isn't measured for all threshold values. Because of this reason, it is preferred 225 mutual information value rather than AUC value. Table 4 represents four threshold values maximizing mutual information for each test. Table 4 doesn't contain the threshold 165 of I. 226 Turbidimetric test and the threshold 197 of I. Turbidimetric test. These threshold values have 227 228 the highest sensitivity and specificity, but they do not have the highest mutual information 229 values. These results prove that, for the overall quality, neither sensitivity nor specificity but 230 the results of mutual information should be examined. Alternative threshold values can be 231 obtained by using information theory.

232 233

Threshold Values		I(D;T)	
I. Turbidimetric	II. Turbidimetric	I. Turbidimetric	II. Turbidimetric
173	102	0.70	0.41
142	118	0.67	0.41
185	124	0.64	0.40
171	101	0.64	0.39

#### Table 4. Mutual information of two tests for different threshold values

234

#### 235 **4. CONCLUSION**

In this study; ROC which is a long-standing method for the evaluation of the diagnostic test
 performance and information theory which has been used recently to evaluate the diagnostic
 test performance are presented in detail.

This study aims to investigate which Turbidimetric test has better performance. This 239 240 performing test is going to be conducted during the study in order to demonstrate whether it can be an alternative to Nefelometric test which is currently the gold standard for the 241 242 diagnosis of rheumatic disorder. Because of this reason, AUC of Nefelometric test is equal to 243 1. The Turbidimetric tests' performances are examined using ROC and information theory. 244 With regard to AUC values, it is concluded that I. Turbidimetric test is more likely to show the 245 similarity to Nefelometric test in comparison with II. Turbidimetric test. Using I. Turbidimetric 246 test has financial benefits to clinicians, since it is less expensive in contrast with Nefelometric 247 test.

248 As a result of Information Theory analysis, the threshold value of 173 is the largest percent 249 correct value which maximizes mutual information. Based on this largest percent correct 250 threshold value, it can be deduced that 0-200 UI/mI reference interval which is mentioned in the medicine literature for Nefelometric test can be replaced with a "new" 0-173 UI/ml 251 252 reference interval. The use of this new reference interval provides more accuracy and leads 253 to less error in the diagnosis of ASO values. As a conclusion of the study, it is recommended 254 to the clinicians to implement I. Turbidimetric test with a new reference interval for the 255 diagnosis of rheumatic disorder.

256 It is aimed that this study will hopefully give various points of view to the researchers who 257 want to make research on this subject by explaining how the tests used for the diagnosis of 258 various diseases are evaluated with this way.
