Technical Efficiency of Chilli Pepper Production in Kaduna State, Nigeria: A Stochastic Production Frontier Approach

Abstract

Aims: Aims of the study were to describe socio-economic characteristics of chilli pepper farmers and determine the technical efficiency of chilli pepper producers in Kaduna state.

Study Design: Primary data were collected from chilli pepper producers through the use of structured questionnaires.

Place and Duration of Study: This study was carried out in three local government area in Kaduna state, Nigeria between August and November 2014 cropping season.

Methodology: Purposive and random sampling techniques were employed for data collection.

Results: the study revealed that 37.5% of the respondents fall within the age of 30-39 years. The 53% had formal education. The household size ranged from 6-10 persons, majority of the farmers (72%) of chilli pepper farmers do not participate in any chilli pepper related cooperative association, and the result shows that 98.5% of chilli pepper farmers financed their production from personal savings. The data revealed that (58.5%) of chilli pepper farmers have extension visit; Results indicated that except for labor and agro-chemical, all other factors were significant ($P < 0.01$, $P > 0.1$). The mean technical efficiency is 90% .

Conclusion: The findings of the study revealed that none of the sample chilli pepper farmers reached the frontier threshold. Thus, within the context of efficient agricultural production, output can still be increased by 10% using available inputs and technology. It was therefore recommended that timely and adequate supply of fertilizer should be made available to farmers at affordable price in order to enhance the production of chilli pepper production.

Key words: Technical efficiency, chilli pepper, stochastic frontier production and Kaduna state.

1. Introduction

Agriculture in Nigeria is dominated by the small scale farmers who are engaged in the production of the bulk of food requirements of the country (1). In spite of the fact that these small scale farmers occupy a unique and pivotal position, they belong in the poorest group of the population and as such cannot invest much on their farms (1). According to (2), the vicious circle of poverty among these farmers has led to the unimpressive performance of the agricultural

sector. Thus, resources must be used much more efficiently, which entails eliminating waste, thereby leading to increase in productivity and incomes (3).

Chilli pepper (*Capsicum frutescens*) is a high value crop that is grown for cash by farmers all over the world (4). Nigeria is known to be one of the major producers of pepper in the world accounting for about 50 percent of the African production (5).

Nigeria has good soils and weather that can readily support the growth and production of pepper. Pepper grown in Nigeria is in high demand because of its pungency and good flavour. It can readily be dried, ground and packaged for export. Investing in pepper production is one of the ways of sourcing for foreign exchange (6). Exportation of pepper in Nigeria has once been reported to be a lucrative business (5). The major area for its production is the Northern region between latitudes 10°N and 12°30'N. Pepper is utilized mostly for culinary purposes and seasonings. It also has medicinal uses, internally as a stimulant and carminative and externally as a counter-irritant (7).

Scarcity of resources has led to production economists to think about the reallocation of existing resources to have more output with given level of input combinations or to produce a prescribed level of output with the minimum cost without changing the production technology (8). Similarly, the measurement of the productive efficiency in agricultural production is an important issue because it gives pertinent information for making sound management decision in resource allocation. Except for a few descriptive studies, econometric analysis has yet to be conducted to examine the production function for chilli cultivation and its potential for future improvement.

Considering the above facts, the study was undertaken, to determine the level of technical efficiency of the chilli pepper producing farmers, to analyze the status of resource allocation.

2. Materials and Method

2.1 Study Area

The study was conducted in three local government areas of Kaduna state namely Ikara, Kubau and Soba. These local government areas are located in the Northern guinea savannah ecological zone of Nigeria and the choice of these local government areas were made because of the reasonable numbers of chilli pepper farmers in the areas (9).

Kaduna state lies between latitudes 09° 02' and 12° 32' North of the equator and between longitudes 06° 15' and 08° 50' East of the prime meridian. The state shares boundaries with Katsina and Kano state to the north, Plateau to the north east, Nasarawa and Abuja to the south and Niger and Zamfara state to the west (9). The state has a total land area of about 4.5 million hectares, with an estimated total arable land of about 2.02 million ha comprising 1.94 million ha upland and 0.08 million ha lowland. There are two distinct seasons in the state namely wet and dry seasons. Wet season generally spans from April to October, while dry season falls between October to March. The average rainfall is about 1,482 mm, while temperature ranges from 35°C-36°C during the humid period to as low as 10°C-23°C during the hamattan periods of November – February (9).

Kaduna state vegetation is divided into Northern Guinea Savanna and Southern Guinea Savanna. The soil is developed from undifferentiated complex igneous and metamorphic rocks. The fine top soil couple with reasonable organic matter in it enhances the fertility status, especially the southern part of the state. The physical properties of the soil are moderately good and allow continuous cropping for variety of crops. The total number of households in the state that grow pepper in 2011 stood at 84,471 (9).

2.2 Sampling Procedure

A multi stage sampling technique was employed to select the respondents for the study. In the first stage, Ikara, Kubau and Soba local government areas were purposively selected out of local government areas in the state on the basis of being the most prominent producing areas of chilli pepper in the state (9). In the second stage two villages were purposively selected from each of the three local government areas because of the large number of chilli pepper farmers in the areas. In the third stage simple random sampling non replacement method was employed to select 10 percent out of the population of chilli pepper farmers in each of the villages, this represent a sample of 200 respondents used for the study.

2.3 Data Collection and Analysis

Primary data was use for this study. The interview method of data collection with the aid of structured questionnaire was used to obtain information from the selected farmers in the study area. Data collection was centered on socio-economic characteristic of the farmers such as age, gender, household size, educational status, farming experience, amount of credit, access to extension service, cooperative membership, farm size, quantities and prices of various production inputs used by the farmers.

2.4 Model Specification

Empirical model specification for the determinants of technical efficiency is as follows;

$$\ln Y = \beta_0 + \beta_1 \ln X_{1i} + \beta_2 \ln X_{2i} + \beta_3 \ln X_{3i} + \beta_4 \ln X_{4i} + \beta_5 \ln X_{5i} + (V_i - U_i)$$

Where:

$\ln$ = the natural logarithm

Y = output of chilli pepper (kg)

β_0 = constant term

$\beta_1 - \beta_5$ = regression coefficients

X_1 = farm size (ha)

X_2 = quantity of seed (kg)

X_3 = quantity of fertilizer (kg)

X_4 = total labour used (man days)

X_5 = agrochemical (litre)

V_i = random errors outside the farmers control.

U_i = technical inefficiency effects.

120 The determinant of technical inefficiency is defined by:

121

$$122 \quad U_i = \delta_0 + \delta_1 \ln Z_1 + \delta_2 \ln Z_2 + \delta_3 \ln Z_3 + \delta_4 \ln Z_4 + \delta_5 \ln Z_5 + \delta_6 \ln Z_6 + \delta_7 \ln Z_7$$

123 Where:

124 U_i = inefficiency effects

125 δ_0 = constant

126 δ_1 - δ_7 = Parameters to be estimated.

127 Z_1 = age of farmer (years)

128 Z_2 = formal education (years of formal schooling)

129 Z_3 = household size (number of people)

130 Z_4 = farmers experience (number of years in chilli pepper production)

131 Z_5 = pepper related cooperative membership (years of participation)

132 Z_6 = amount of credit (amount of credit obtained)

133 Z_7 = extension visit (number of visit)

134 **3. Results and Discussion**

135 The study revealed that 37.5% of the chilli pepper farmers were within the age range of 30-39
 136 years with mean of 46 years. This implies that, the farmers are still strong and active and they
 137 can participate actively in farming activities is also in line with the findings of (10) younger
 138 farmers are more flexible to new ideas and risk; hence they are expected to adopt innovations
 139 more readily than older farmers. Education the result shows that 47% of chilli pepper farmers
 140 had no formal education, while 30% of the respondents are within 1-6 years of education which
 141 means they had only primary education, and 15.5% had secondary education while 7.5% had
 142 tertiary education. This indicates that the farmers' educational level is low. This finding is at
 143 variance with (11).

144 The majority of the farmers (33.5%) had household size that ranged from 6-10 persons. The
 145 average household size was 11 persons implying that there is appreciable number of family
 146 labour supply to accomplish various farm operations. Farming experience is another important
 147 socio-economic factor that can bring about increase in productivity. The result shows that 24%
 148 of chilli pepper farmers had an experience of 6-10 years, 18.5% of the respondents are within 11-
 149 15 years of farming experience while 17.5% of the respondents are within 1-5 years of farming
 150 experience which means that chilli pepper farmers in the study area had vast experience in their
 151 production.

152 The result in cooperative membership shows the numbers of years spent in cooperative. About
 153 (72%) of chilli pepper farmers do not participate in any chilli pepper related cooperative
 154 association and the reasons for this include: being small scale and unawareness of any
 155 association while 28% participated with average of 1.7years. The effect of this result is that most
 156 of the chilli pepper farmers in the study area do not enjoy the assumed benefits accrued to co-
 157 operative societies through pooling of resources together for a better expansion, efficiency and
 158 effective management of resources and for profit maximization. (12) and (13) Stated that
 159 membership of cooperative societies has advantages of accessibility to micro-credit, input
 160 subsidy and also as avenue in cross breeding ideas and information.

The result in table shows that 98.5% of chilli pepper farmers financed their production from personal savings while 1.5% sourced credit, through Bank of agriculture. The low access to credit could be attributed to the fact that government seldom grants financial credit to farmer. (12) asserts that credit is a very strong factor that is needed to acquire or develop any enterprise; its availability could determine the extent of production capacity. It also agrees with findings of (14) who noted that access to micro-credit could have prospect in improving the productivity of farmers and contributing to uplifting the livelihoods of disadvantaged rural farming communities. The result revealed that 41.5% of chilli pepper farmers in the study area have no extension visit while (58.5%) have extension visit with average of 1 visit, this could be attributed to increased of extension agent-farmers' ratio by the KADP in the study area.

3.1 Maximum likelihood estimates results of the frontier production function of chilli pepper production

The variances of the technical efficiency presented in table indicate that, the sigma-square and the gamma were both positive and significantly different from zero at 1% and 5% level of probability respectively. This indicates a good fit and the correctness of the specified distribution assumption of the composite error term. Hence the use of the stochastic frontier function estimated by the Maximum Likelihood Estimates procedure is suitable for the data.

However, the estimated coefficients of all the parameters of production function (farm size, seed and fertilizer) were positive and significant at 10%, 1% and 1% level of probability respectively, except labour and agrochemical which were negative and not statistically significant. The average technical efficiency for the farmers is 0.90 implying that, on the average the respondents are able to obtain 90% of potential output from a given mixture of production inputs. Thus, in a short run, there is minimal scope (10%) of increasing the efficiency, by adopting the technology and techniques used by the best chilli pepper farmer. The result shows that the coefficient of farm size (β_1) was positive and significant at 10% level of probability. This implies that an increase in farm size would result to an increase in the quantity of chilli pepper produced in the study area by coefficient of variation (0.213).

The estimated coefficient for seed (β_2) was 0.636 which is positive and statistically significant at 1% level probability. This conforms to the *a priori* expectation that increase in seed would bring about increase in output. The estimated 0.636 elasticity of seed implies that increasing the use of seed by 1% will increase chilli pepper output by less than 1% which means, all things being equal the output is inelastic to changes in the quantity of seed used. The significance of seed quantity is however, due to the fact that seed determines to a large extent the output obtained. If

199 correct seed rates and quality seeds are not used, output will be low even if other inputs are in
200 abundance. This is in line with the findings of (15) who observed that the estimated coefficient
201 of seed inputs was positive as expected and significant at 1% level implies that the more seed is
202 applied the better the output.

203 The production elasticity of output with respect to quantity of fertilizer (β_3) was 0.053 which is
204 positive and statistically significant at 1% level. This implies that a 1% increase in fertilizer will
205 increase chilli pepper output by 0.05%. Fertilizer is a major soil augmenting input because it
206 improves the quality of soil by raising yields per hectare. This study is in agreement with the
207 findings of (16) and (17). A timely and efficient management and utilization of fertilizer input
208 will improves the quality and quantity of yields per hectare.

209 The estimated coefficients of Labour (β_4) and agrochemical (β_5) were negatively related with the
210 output and not statistically significant from zero. These implies additional use of labour and
211 agrochemical would reduce the output by the coefficient (-0.085) and (-0.069) respectively. This
212 is against the *a priori* expectation and the negative effect of these inputs (labour and
213 agrochemical) could be attributed to overutilization of the resource in chilli pepper production.

214 The estimated result of the inefficiency model is contained in Table 4. A negative sign on a
215 parameter means that the variable reduces technical inefficiency, while a positive sign increases
216 technical inefficiency. The results shows that age of the farmers, level of education, farming
217 experience, credit obtained and extension contact have a negative sign, and therefore reduce
218 technical inefficiency (or increase technical efficiency) while household size and cooperative
219 association have positive signs, implying that they increase technical inefficiency (or reducing
220 technical efficiency).

221 The coefficient of farmer's age was inversely related to technical inefficiency and not
222 statistically significant. This had a positive influence on technical efficiency in chilli pepper
223 farming in the study area. This study is in conformity with the *a priori* expectations that age of
224 the respondent's increases as the technical inefficiency decreases. This finding is in difference
225 with (18) who in their study of small scale farmers in Nigeria found age to be positively related
226 to inefficiency.

227 The estimated coefficient of education has a negative sign and not statistically significant. This
228 indicates that level of education attained increase technical efficiency. This could probably be
229 explained by the fact farmers probably employ their educational advantages as opportunity to
230 develop their production capability and inferably would be ready to adopt innovations and
231 technologies for improved productivity and is in line with the public assertion that education
232 advancement bring about better technical efficiency in farming as a result of easy understanding
233 of farming technologies and adoption of new innovations.

234 The coefficient of household size in the inefficiency model is positive but not significantly
235 different from zero. This may be due to the fact that farmers with large household size has more
236 people to feed with less income left to acquire inputs for production. These findings agree with
237 the findings of (19) there is a positive and significant relationship between household size and
238 farmers' efficiency in production. However, the absolute number of people in a certain family
239 cannot be used to justify the potential for productive farm work. This is because it can be
240 affected by some important factors namely; age, sex and health status. This shows that a

reasonable number of the respondents have a large household size. Higher household size provides enough persons for family labour and less money will be needed to pay for hired labour. The coefficient of farming experience in the inefficiency model is negative and significant at 10% level of probability. This implies that farming experience reduces technical inefficiency and contributes positively to technical efficiency in chilli pepper farming in the study area.

The estimated coefficient of cooperative association has a negative sign related to technical inefficiency and significantly different from zero at 5% level of significance. This implies that it reduce technical inefficiency (or increasing technical efficiency), despite the low participation of the farmers in cooperative membership in the study area. Extension contact also has a negative sign related to inefficiency and significantly not different from zero. This implies that it increase technical efficiency (or reducing technical inefficiency). This is in line with several studies that found extension to be positively related with technical efficiency (20).

The estimated coefficient of credit accessibility has negative estimate related to inefficiency and not statistically significant. (12) Asserts that credit is a variable that is needed to acquire or develop any enterprise; its availability could determine the extent of production capacity. It also agrees with findings of (14) who noted that access to micro-credit could have prospect in improving the productivity of farmers and contributing to uplifting the livelihoods of disadvantaged rural farming communities.

Table 4: Result of maximum likelihood estimates frontier technical efficiency of chilli pepper production

Variables	Parameters	Coefficients	Std. error	T-Value

3.2 Frequency distribution of technical efficiency estimates of chilli pepper farmers

The frequency distribution of the technical efficiency estimates for chilli pepper farmers in the study area as obtained from the stochastic frontier model presented in Table 5. It was observed from the study that 12% of the farmers had technical efficiency (TE) of less than 0.81 level efficiency while 88% of the farmers operate at 0.81 and above level efficiency. The farmer with the best and least practice had a technical efficiency of 0.98 and 0.74 respectively. This implies that on the average, output fall by 2% from the maximum possible level due to inefficiency. Also 90% of the farmers were estimated to have technical efficiency exceeding 0.8, indicating there are some 10% technical inefficient farmers in the study area.

The study also found that for the average farmer in the study area to achieve technical efficiency of his most efficient counterpart, he could realize about 10.2% ($1 - 0.90/0.98 \times 100$) cost savings while on the other hand, the least technically efficient farmers will have about 26.5% ($1 - 0.74/0.98 \times 100$) cost savings to become the most efficient farmer.

Table 5: Frequency distribution of technical efficiency from the stochastic frontier model

Technical efficiency level	Frequency	Percentage
0.61-0.80	24	12
0.81-1.00	176	88
Total	200	100
Mean	0.90	
Min	0.74	
Max	0.98	

4. Conclusion

The farm specific technical efficiency distribution reveals that none of the farmers achieved the maximum efficiency level. Thus, within the context of efficient agricultural production, output can still be increased by 10% using available inputs and technology.

4.1 Recommendations

Cooperative association is one of the variables that is significant, it is therefore, recommended that chilli pepper farmers should join cooperative societies to enable them procured fertilizer at subsidized rate.
