Useful Working Fluids for Feasible Super Efficient Trilateral Cycles

This work studies the feasible trilateral cycles operating with some working fluids characterised by the process of conversion heat into mechanical work undergoing controlled isothermal expansion path functions in the supercritical region slightly above the critical point, and rejecting heat to the heat sink at such temperatures. The relevance of the studied working fluids resides in that the trilateral cycle performance can be increased by using the ability of the selected working fluids to exhibiting very high thermal efficiency when operating within the vicinity of its critical point.

The analysis of the trilateral cycle undergoing the transformation of heat to mechanical work on the basis of an isothermal expansion has been carried out. The achieved results reveals that the studied working fluids, provides us an exceptional high thermal efficiency.

Keywords: Carnot factor, Low isobaric slope, Isothermal expansion, Thermal efficiency, Trilateral cycle.

1. INTRODUCTION

During the last decade, growing interest has been observed in utilizing low and medium temperature heat sources, mainly due to its availability from oceans, solar, geothermal and industrial residual heat sources. In this way recently TCs (trilateral cycles) [1-3] are being implemented. Thus, for example, the TC performance has been researched for ammonia-water as working fluid in [2] and ORCs and TCs have been thermodynamically compared in [3]. The author presents a comparison of optimized systems with trilateral cycles with water as working fluid and optimized organic Rankine cycles, where the optimization criterion is the exergy efficiency for power production being the ratio of the net power output to the incoming exergy flow of the heat carrier. The author claims that the exergy efficiency for power production is larger by 14% - 29% for the trilateral cycle than for the ORC.

Whilst ORC and Kalina cycles are used already in existing power plants, the TC, although theoretically mature, it is still under technical development [1]. The components to implement a conventional TC are similar to those in the ORC system except that the working fluid at the entrance of the TC expander (turbine) is a saturated liquid. As consequence, the state of the working fluid at the expander exit is a two-phase mixture. As the thermodynamic mean temperature at which heat is received is comparatively lower for the TC, the thermal efficiency for this cycle is lower than that for the ORC, for the same temperature limits. The performance of a trilateral cycle has been recently analysed in [4]. Also investigates and compares it with those for the ORC (organic Rankine cycle) and the Kalina cycle, focused on thermodynamics and thermo economics aspects. The results for the TC indicate that an increase in the expander inlet temperature leads to an increase in net output power and a decrease in product cost for this power plant, whereas this is not the case for the ORC system.

Quasi-isothermal compression based reciprocating engines as well as Quasi-isothermal expansion based power cycle engines have been recently developed. In this way, M.W. Coney et al., [5] presented the analysis of a novel concept for a high efficiency reciprocating internal combustion engine called as the isoengine and its cycle, where the maximum net electrical plant efficiency has been predicted to approach about 60% on diesel fuel and 58% on natural gas. They concluded that the key to the high electrical efficiency is the quasi-isothermal compression of the combustion air in cylinders, saving compression work and allowing the recovery of waste heat back into the cycle, mainly from the exhaust gas by means of a recuperator. On the other hand, Opubo N et al. [5], investigated some vapour power cycles for quasi-isothermal expansion instead of adiabatic expansion, taking advantage of the fact that quasi-isothermal expansion has the advantage of bringing the cycle efficiency closer to the ideal Carnot efficiency, with the

drawback of requiring heat to be transferred to the working fluid as it expands. The authors claimed that the comparison the specific work output to more standard Stirling engines using gas is higher. The research effort in this work is focused on trilateral thermal cycles operating under quasi-isothermal expansion instead of adiabatic expansion. Throughout this contribution it will be shown that for low relative operating temperatures the thermal efficiency exceeds the Carnot factor, which makes this thermal cycle very suitable for exploiting the heat to power conversion cycles with low grade residual heat.

However, in the present work the closed isothermal path functions carried out in the TCs, are appropriated to operate at relative low temperatures, being based on a completely different thermal cycle concept in comparison with the conventional Carnot based thermal cycles, not only structurally but also in terms of CF (Carnot factor) constraints, which can be surpassed in some particular operating conditions [6 - 7].

Thus, the objective of the study is to efficiently convert low temperature heat mainly from ocean thermal, solar thermal and low grade heat from industrial residual power sources by means of the proposed TCs into electric energy. As it has been indicated, the proposed conversion method is based on a different thermodynamic cycle: a non condensing mode closed processes based TC with or without regeneration. With this contribution, most of the low grade rejected heat may be converted into mechanical work at acceptable thermal efficiency by applying a TC whose thermal efficiency is not restricted by the CF such as mentioned in [7 - 9].

2. ANALYSIS OF THE TC UNDERGOING AN ISOTHERMAL EXPANSION.

In order to analyse the Isothermal ideal cases, let's consider the displacement of the piston under different path functions as shown in Fig.1, for the following processes denoted as
-Isothermal process (constant temperature)

Fig 1, depicts the mechanical work performed under isothermal thermodynamic transformations when evolving from the state point i to the state point i+1, denoted as the state point 1 and state point 2 respectively.

Fig. 1. Mechanical work performed undergoing an isothermal path function.

2.1. The background of the work performed under an isothermal path function.

According to the scheme depicted in Fig. 1, follows that the mechanical work performed by a piston along its full stroke can be described by means of a general expression as

$$W_{1-2} = \int_{V_1}^{V_2} p \cdot dV \quad (1)$$

furthermore, considering a closed process undergoing an isothermal transformation, it follows that

$$p \cdot V = p_1 \cdot V_1 = p_2 \cdot V_2 \rightarrow \frac{V_1}{V_2} = \frac{p_2}{p_1} \rightarrow p = \frac{p_1 \cdot V_1}{V} = \frac{R \cdot T_1}{V} \quad (2)$$

thus the mechanical work delivered under an isothermal transformation is

$$W_{1-2} = p_1 \cdot V_1 \int_{V_1}^{V_2} \frac{dV}{V} = p_1 \cdot V_1 \cdot \ln \frac{V_2}{V_1} = p_1 \cdot V_1 \cdot \ln \frac{p_1}{p_2} = R \cdot T_1 \cdot \ln \frac{p_1}{p_2} \quad (3)$$

The mechanical work described by Eq. (3) is realisable under the condition that the load (motion resistance) follows the profile defined by Eq. (2).

2.2. The proposed TC undergoing isochoric heat absorption, isotherm expansion and isobaric heat rejection based path functions

The proposed TC obeys the processes included between the state points defined in Table 1. In this way, Fig. 3 shows the T-s and p-V diagrams of a feasible TC undergoing a closed process based transformation for converting heat into mechanical work, where Fig. 2(a) and Fig. 2(b), depicts the isothermal transformation for the task of heat to work conversion.

98

According to the information provided by the Table 1 and the Fig. 2, the transformations associated to each path function of the TC are summarised as follows:

100
101
102

103
104
105

Fig. 2. The T-s and p-V diagrams of the TC undergoing a TC isothermal expansion for converting heat into mechanical work.

108

Leg (1)-(2):

Correspond to a closed isochoric heating process. The amount of heat added from an external heat source at constant volume q_v is

112

$$W_{12} = 0, \quad q_{12} = u_2 - u_1 = C_v \cdot (T_2 - T_1) = q_v \quad (4)$$

114

Leg (2)-(3):

115

Correspond, to a closed isothermal heating process. Consequently the internal energy remains constant so that the total heat added q_T is converted into mechanical works since ideally there are not internal energy changes, and consequently,

$$u_{23} = 0, \text{ and } q_T = W_{23} \quad (5)$$

$$\text{Since } \frac{p_2}{p_1} = \frac{V_3}{V_1} = \frac{X_1 + X_3}{X_1} = 1 + \frac{X_3}{X_1}$$

follows that

$$q_{23} = W_{23} = p_2 \cdot v_2 \cdot \ln\left(\frac{p_2}{p_1}\right) = R \cdot T_2 \cdot \ln\left(\frac{p_2}{p_1}\right) \quad (6)$$

which can be also expressed as function of the piston location (X) along the cylinder stroke according to the expression (7)

$$q_{23} = W_{23} = p_2 \cdot v_2 \cdot \ln\left(\frac{V_3}{V_1}\right) = R \cdot T_2 \cdot \ln\left[1 + \frac{X_3}{X_1}\right] \quad (7)$$

Leg (3)-(1):

Correspond to a closed isobaric process in which the working fluid is cooled. There is not mechanical work so that the rejected heat is coming from the internal energy according to the function

$$W_{31} = 0, \quad q_{31} = u_3 - u_1 = C_v \cdot (T_2 - T_1) = C_v \cdot (T_3 - T_1) = q_p = q_o \quad (8)$$

According to the expressions (7) - (9), the thermal efficiency of the TC undergoing a closed isothermal expansion is given as

$$\eta = 1 - \frac{q_o}{q_i} = 1 - \frac{q_{31}}{q_{12} + q_{23}} = 1 - \frac{q_{31}}{q_{13}} = \frac{W_{23}}{q_{13}} \quad (9)$$

Therefore the thermal efficiency of an isothermal expansion based TC can be expressed analytically, as

$$\eta = \frac{W_{23}}{q_{13}} = \frac{W_{23}}{(u_2 - u_1) + W_{23}} = \frac{R \cdot T_2 \cdot \ln\left[1 + \frac{X_3}{X_1}\right]}{(u_2 - u_1) + R \cdot T_2 \cdot \ln\left[1 + \frac{X_3}{X_1}\right]} \quad (10)$$

Since ideally the heat added to the transformation (2)-(3) is converted into mechanical work, the thermal efficiency defined in (11) exhibits a strong dependence on the difference of temperatures ($T_2 - T_1$). Apparently, the thermal efficiency tends to the unity when such temperature difference tends to zero. However, real gases behaviour differs from this model.

Furthermore, even that

$$q_v = q_{12} = u_2 - u_1 = C_v \cdot (T_2 - T_1),$$

$$q_o = q_p = q_{31} = u_3 - u_1 = C_v \cdot (T_3 - T_1),$$

and

$$T_3 = T_2,$$

follows that

$$q_v = q_o \quad (11)$$

and

$$q_i = q_v + q_T = q_v + W$$

Consequently, since

$$\eta = \frac{q_i - q_o}{q_i} = \frac{q_v + W - q_o}{q_i} = \frac{q_v + W - q_v}{q_i} = \frac{W}{q_v + W}$$

follows that

$$\lim_{q_v \rightarrow 0} (\eta) = \lim_{q_v \rightarrow 0} \frac{W}{q_v + W} = 1 \quad (12)$$

Eq. (12), as well as Eq. (10) suggests us that considering a reversible TC, when T_2 approaches T_1 , or q_v approaches zero, the thermal efficiency tends to the unity. However, since $q_v > 0$, then, $\eta < 1$, as stated the second law.

3. A CASE STUDY

This section deals with the exploration and analysis of a case study in which a TC composed by closed systems based transformations is applied on the conversion of heat to mechanical work undergoing an isothermal expansion based path function to change from state point 2 to state point 3.

3.1. The structure of the TC undergoing isothermal expansion to convert heat into mechanical work

The Fig. 3 represents a closed processes based TC implemented by means of a single effect cylinder in which Fig. 3(a) shows the single effect cylinder, Fig. 3(b), shows the sequence of processes carried out to complete the cycle, and Fig. 3(c) shows the corresponding p-V and T-s diagrams assuming isothermal expansion.

Fig. 3. A closed processes based TC implemented with a single effect cylinder. (a), single effect cylinder. (b), process sequence. (c), the p-V and T-s diagrams.

The TC shown In Fig 3 consists of a single effect cylinder-actuator which could operate optionally with several working fluids including but not limited to carbon dioxide, helium, hydrogen and nitrogen, as well as other gases that remain at gaseous state at ambient temperature. The cylinder is equipped with heating and cooling facilities. The piston rod could drive a reciprocating hydraulic pump for instance or any other load type. Although not analysed in this work and consequently not represented in Fig 3, the possibility of regenerating some residual heat exits due to the fact that the residual heat corresponding to the working fluid temperature at the end of the expansion could be reused. Consequently, the possibility of increasing the thermal efficiency by regeneration is a real fact. The thermal cycle depicted in Fig 3 can be easily understood by observing the associated table as well as the p-V and T-s diagrams shown in Fig. 3 (c).

In the associated table of Fig. 3 (b) the ports X and Y means the heater and cooler heat flows. Thus $X = 1$ means that heat is entering to the cylinder, while $Y = 1$ means that heat is being rejected from the cylinder to the environment. $X=Y=0$ indicates no heat transfer activity.

Considering the active chamber of the cylinder depicted in Fig. 3 (a), and the T-s diagram shown also in the Fig. 3 (c), the TC starts in the state point 1, with a working fluid under a pressure, temperature, specific volume and entropy corresponding to the state point 1. After some heat has been added (q_{12}) at constant volume (isochoric process), the pressure, temperature and entropy corresponds to the state point 2. The transformation 2-3 undergoes constant temperature, so that the heat added (q_{22}) is converted theoretically into mechanical work at constant temperature (isothermal process), since the internal energy will remain constant along the transformation 2-3. The last transformation corresponds to the heat rejection q_{31} towards the heat sink which might be the environment.

As pressure decreases as consequence of the isothermal expansion, the mechanical load reacting against the piston rod is balanced to satisfy the condition of constant internal energy along the piston stroke until the bottom dead centre.

After expansion has finished in the state point (3), the piston initiates the way back towards the point (1) (the top dead centre) at constant pressure, while is being cooled, so that the cycle is completed.

3.2. The selected working fluids

Table 1. The selected working fluids, showing the critical conditions and the maximum allowable operating temperature from [10]

WF	T_c (K)	p_c (bar)	T_{max} (K)
ethylene	282.35	50.418	450
xenon	289.73	58.42	750
CO ₂	304.01	73.773	2000
ethane	305.32	48.722	675
R41	317.28	58.97	425
R218	345.02	26.4	440
R143a	345.86	37.61	650
R32	351.26	57.82	435
propylene	364.21	45.55	575
propane	369.89	42.512	625
R134a	374.21	40.593	455
RC318	388.38	27.775	623
ammonia	405.4	113.33	700
methanol	512.6	81.035	620
ethanol	513.9	61.48	650
water	647.1	220.64	2000

Table 2. Potential working fluids, showing the critical conditions and the maximum allowable operating temperature from [10]

WF	T_c (K)	p_c (bar)	T_{max} (K)
Toluene	591,75	41,26	700
Hexane	507,82	30,34	600
Heptane	540,13	27,36	600
Decane	617,70	21,03	675
Cyclo hexane	553,64	40,75	700
Acetone	508,10	47,00	550

The working fluids shown in Table 1 under study were selected after a search process from a vast amount of available fluids according to [10] such as to satisfy certain conditions in the supercritical region above the critical point. Furthermore, the required conditions are defined for a region located at the vicinity of the critical point as:

the isobaric slope shown in Fig. 4 defined according to the T-s diagram,

$$\frac{dT}{ds} \rightarrow 0, \quad (13),$$

Fig. 4. T-s diagram for CO₂ as working fluid, operating in the vicinity of the critical conditions, for which the slope of the isobars (dT/ds) approaches zero.

the Isobaric slope shown in Fig. 5 defined according to the T-h diagram,

$$\frac{dT}{dh} \rightarrow 0, \quad (14)$$

Fig. 5. T-h diagram for CO₂ as working fluid, operating in the vicinity of the critical conditions, for which the slope of the isobars (dT/dh) approaches zero.

and the isothermal slope shown in the Fig. 6 defined according to the p-h diagram

$$-\frac{dp}{dh} \rightarrow 0 \quad (15)$$

Fig. 6. p-h diagram for CO₂ as working fluid, operating in the vicinity of the critical conditions, for which the slope of the isotherms (-dp/dh) approaches zero.

Such characteristic, shown in Figs. 4, 5 and 6 for the case of carbon dioxide considered as real gas is used to define the region of maximum thermal efficiency. The consequence of this characteristic is

summarised as follows: That is, the selected working fluids exhibit the characteristic of the highest thermal efficiency when operating within a region above its critical point.

3.3. Modelling the TC

The TC modelling task has been carried out with data extracted from [10] (REFPROP) and the tool Engineering Equation Solver (EES). The REFPROP consists of an up-to date data base used for property calculations and is available in commercial software packages whose library makes use of Helmholtz fundamental equation correlations to determine fluid properties from the highest-accuracy published data available in literature. Furthermore, the database can be linked with software based tools such Visual Basic, Fortran, C, and even spread sheets to help the automation of data processing. In the proposed case study the data necessary to carry out the performance analysis is presented in Table A1 of the appendix A.

For the analysis of the cycle with the considered working fluids exhibiting the characteristics shown in Table 1, the necessary tests has been carried out to study the cycles performance and behaviour.

4. MAIN RESULTS OF THE ANALYSED CASE STUDY

The results of the study achieved using the EES yield the values of Table 3 using the data shown in Table A1 of the appendix A. The data used in the case study for the study of the potential working fluids is taken from reference [10]. Cycle computation is referred to the T-s diagram of Fig. 7 for a non regenerative TC. The values of the state variables corresponding to each state point for all considered working fluids are shown in the Table A1 of the appendix A, where for every working fluid a set of top and bottom temperatures has been considered, as shown in Table 3. Table 3 shows for every selected working fluid

- critical temperature T_c (K),
- bottoming TC temperature T_1 (K),
- topping TC temperature T_2 (K),
- critical TC pressure p_c (bar),
- bottoming TC pressure p_1 bar),
- topping TC pressure p_2 (bar),
- thermal efficiency η (%)
- Carnot factor CF(%), and
- specific work W (kJ/kg)

Fig. 7. The layout of the TC for carbon dioxide as working fluid, operating in a region above the critical point

In Table 3, the WFs are represented by its critical temperature in ascendant order. The bottoming temperature $T_1(K)$ is chosen below ten degrees from the critical temperature. The topping temperature is chosen between 20-30 degrees above the bottoming temperature. The bottoming pressure is chosen between 2-4 bar above the critical pressure, and the topping pressure p_2 (bar), is associated with the topping temperature. The topping TC temperature has been chosen to fulfil the characteristic of high thermal efficiency in the region above the critical point. Since the ratio of the bottoming to the topping temperatures is low, the corresponding CF is also low. However since the thermal efficiency of the TC is independent of the CF, the thermal efficiency is significantly high.

In order to facilitate the analysis of the results to extract useful conclusions, Table 4, shows the studied working fluids ordered in descendent order by thermal efficiency, specific work, topping temperature and topping pressure. This table is useful to highlight the working fluid that satisfies the desired conditions. Thus, focusing on the thermal efficiency follows that the best WF is water, whose thermal efficiency approaches 87%, and if focusing on the specific work, follows that the specific work approaches 2180 kJ/kg. The available topping temperatures associated with the residual heat source is also important to select the appropriated WF. Thus, water requires a power source capable to heat the working fluid till 675 K, which undergoes a topping pressure of 273 bar. Consequently, the same considerations must be taken into account for the rest of the studied fluids.

Table 3. The performance of a TC operating with the studied working fluids presented in ascendant order by its critical temperature

5. CONCLUSION

Trilateral thermal cycles operating with some working fluids characterised by the process of conversion heat into mechanical work undergoing controlled isothermal expansion path functions in a region above the critical point, have been studied. By means of the study, It has been shown that trilateral cycles performance can be improved by using the ability of the selected working fluids to yield high thermal efficiency when operating within a supercritical region above the critical point.

The objective of the study consisted of highlighting the operating characteristics of potential working fluids operating on a trilateral thermal cycle undergoing isothermal expansion path functions.

As result of the study carried out, some data concerning useful criteria to select the appropriate working fluid as function of the feasible operating conditions, is highlighted. Therefore, taking as performance criteria the thermal efficiency, follows that the top ten working fluids are: Water, R32, R41, R143a, R134a, Methanol, Ethane, Propylene, Ethanol and CO₂, while the thermal efficiency is within the range of 76 % for CO₂ to 87 % for water.

However, taking as performance criteria the specific work, follows that the top ten working fluids are: Water, Ammonia, Propylene, Methanol, R32, R41, CO₂, Ethanol, Ethane and Ethylene, while the specific work is within the range of 350 kJ/kg for Ethylene to 2180 kJ/kg for water.

According to the achieved results it is concluded that water is a working fluid capable to yield the highest thermal efficiency and specific work.

From the analysis of the case study it can be highlighted also the independence of the thermal efficiency with respect to the CF, as well as the high thermal efficiency at low top temperatures with respect to CF.

T_{max}	max. allowable temp. (K)		
u	internal energy (kJ/kg)		
X_1	Initial cylinder volume (m)		
X	Fraction of the piston stroke(m)		
W	specific work (isothermal TC) (kJ/kg)		

Table A1. The state variables of the TC state points for each working fluid using data from [10]

point	T(K)	u(kJ/kg)	s(kJ/kg-K)	p(bar)	v(m³/kg)	Cv(kJ/kg-K)	Cp(kJ/kg-K)
