ABSTRACT

Aims: As part of risk assessment, we **explored** health impacts of consuming polluted water with fluoride in an exposed population in the region of Berka in the mining area of Gafsa. The main objective of this study was to evaluate and prioritize the health risks of **polluted water** with fluoride by the method of Kinney. The secondary objective is to propose a corrective action plan.

Study design: Descriptive.

Place and Duration of Study: The study was conducted in the southwest of Tunisia, in the mining area of south Gafsa (Moulares-Redayef basin) between February and June 2012.

Methodology: The approach adopted in the Health Risk Assessment of water polluted with fluoride is one of the Ranking methods named the method of Kinney which classifies risks according to their severity. It consists on (1) Research of the identified hazards in the population concerned, (2) analyze them, (3) Develop a strategy and (4) Set priorities.

Results: Following this process of health risk evaluation of water pollution with fluoride, we have been able to show that over 50% of the population had presented dental fluorosis and 11% of our population had a very high risk score.

Conclusion: Secondary health risks to polluted water with fluoride were important in our study population and a corrective action plan was proposed. This encourages us to promote the dosage of fluoride in water and the updating of Tunisian standards for drinking waters.

1. INTRODUCTION

14 15

In recent decades, environmental health and its issues have attracted more and more the concern of civil
 society, public authorities, policy makers and whistleblowers [1].

In his research work in hydrogeology, Hamed [2] showed some fluoride rates that exceeded the drinking water standards [3,4] in the region of Berka in the mining area of Gafsa. Fluoride in drinking water is our main source of it [5]. Different absorption levels of fluoride can be estimated by its concentration in the drinking water in various regions, food and beverages consumption, the use of toothpaste etc [5]. In the absence of specific measurements of the population, fluoride exposure is calculated from scenarios based on different lifestyles [5].

Frequent uptake of fluoride can cause osteoporosis and tooth decay. The fluoride can damage the kidneys, bones, nerves and muscles [6]. For this purpose, in this study, we have considered to assess the health risks of drinking polluted water with fluoride in the area of "Berka".

After presentation of the location and the study population, we present the adopted methodology "the method of Kinney" [7] which is one of the "ranking" methods used to classify risks according to their seriousness. For this purpose, we have: (1) prepared a questionnaire through which we collected the necessary data in our study; (2) prioritized potential health risks associated with exposure to fluoride; (3) and assess the health risks related to exposure to fluoride in drinking water. 32

33 2. MATERIAL AND METHODS

34 35

36

2.1 Location of the study

37 The study area is located in the southwest of Tunisia, in the mining area of south Gafsa (Moulares-38 Redavef basin). It covers an area of approximately 300 km². Due to the increasing water demand, the 39 use of groundwater becomes very important. Such demand was caused by the industrial installation of the phosphates exploitation company complex (Compagnie de Phosphates de Gafsa - CPG), the 40 rapid growth of the population and the development of agriculture (several irrigated areas). A portion 41 42 of this basin (about 80 km²: Berka area) is contaminated by discharges from the phosphate mine waste lavatory of Moulares and Redayef and releases from the National Office of Sanitation (ONAS) 43 44 [2].

- The mining area contains a multilayer aquifer system. The main levels with hydrous potentials of this system (major water reservoirs) are represented by the formation of: (1) fractured limestone (carbonate) located in recharge areas (bordering areas), (2) friable sand localized in discharge zones (outlet).
- The hydrogeology of this system is highly influenced by the discharges from phosphate mine waste avatory. In the region of Berka [2], groundwater is used by shallow wells with less than 6 m depth.
- 51 The infiltration of discharges to water table is promoted by the lithological nature of the land which is 52 mainly sandy (high porosity exceeding 35%) [8]. In addition, the region is geographically located in a 53 seismically active region [9]. The locals use groundwater mainly from the shallow water table for 54 drinking and in agriculture.

55 **2.2 Study population**

According to the 2004 census, there were 24 487 inhabitants in Moulares. The region of Berka contains 250 inhabitants. It is a rural area. A primary school is located in the village center educating young children who are a vulnerable exposed population to fluoride. It also has a medical dispensary type I, located 8 km from the delegation of Moulares. In order to assess the health risks of water polluted with fluoride in the region of Berka, we considered taking a sample population of 100 people distributed by age as follows: (1) pre-school child: less than 6 years; (2) school child: 6 to 15 years; (3) Young: 15 to 30 years; Adult: 30 to 50 years; Aged: over 50 years.

63 In this sample population of Berka, we introduced a pre-established questionnaire to gather 64 necessary data required for the health risk assessment of water polluted with fluoride according to the 65 Kinney's model [7].

2.3 Methodology

The used approach in health risk assessment of water polluted with fluoride consists in exploring identified hazards among the study population, analyze them, develop a strategy and set priorities. This approach, the method of "Kinney" [7] is one of the ranking methods that classify risks according to their severity.

- This method from 1976 was named after its inventor, an American researcher; is probably one of the best known [10].
- The kinney method is based on tables giving values depending on three factors; the probability (P), the exposure frequency (F) and the effects (E). The risk index or the risk score (R) is numerically calculated by the following expression: $R = E \times F \times P$.

77 • The probability « P »

- The probability (P) or the (mathematical) risk indicates a prediction and is assigned a reference number from 0.1 to 10 (Table 1.1). 80
 - Frequency « F »

The frequency factor (F) gives an idea of the period of risk exposure. Exposure frequency factors vary
 from 0.5 à 10 (Table 1.2).

100 **3. RESULTS**

101 **3.1 Description of study population**

102 Initially, we planned to take a random sample population of 100 people. During the first going out to 103 the region of Berka, we were able to interview 60 subjects (Table 3). However, the security 104 circumstances prevented us to question the remaining 40 subjects. Fifty-three subjects or 88% of the 105 study population reside permanently in the region of Berka (including 34 are male or 56%; and 26 106 are female or 44%). The health status of individuals participated in this study was described as very 107 good to very poor depending on the participant.

Age	Ν	(%)
Pre-school child (< 6 years)	8	13
School child (6 à 15 years)	12	20
Young (15 à 30 years)	16	27
Adult : (30 à 50 years)	14	23
Aged (> 50 years)	10	17

111

117

112 **3.2 Data regarding fluoride exposure**

Before its connection to the national water distribution utility (SONEDE), the population of Berka was consuming local well water. Currently, some people still use well water due to the difficult access to the public drinking-water distribution system. Fifty-one percent (51%) of our study population consumes mainly well water, the rest consumes tap water since 9 years.

118 **3.3 Risk assessment**

The main clinical manifestations sought in our study population and mean values of risk indexes for each health effect are summarized in Table 4. The thyroid disorder, particularly the goiter was not detected in any of the participants in this study, thus, its mean risk score is low. Event though, few samples are affected by severe neurological damage, its mean risk scores is the highest (74.3) (Table 4).

- 124 Whatever the effect, the average risk indexes per age group, increases proportionally with age 125 (Table 5). Indeed, the higher the age is, the greater the duration of exposure to the pollutant is.
- In our study population, we noted that 7 cases had a very high risk; 4 cases with very severe bone
 fragility and 3 cases with significant neurological damages. The risk score of bone fragility varies
 from 1 to 5 (Table 6).
- For dental fluorosis, attention would be required; especially that 58% (35 cases) of our study population belongs to the category 2. Similarly for the problem of crippling skeletal fluorosis and neurological damage, since 55 to 70 % of our study population belongs to the category 2 (Table 6).

138 139

140 4. COMMENTS AND DISCUSSION

141 **4.1. Health risk assessment**

142 Our results match with those in the literature concerning secondary effects of fluoride. Indeed, in our 143 study population, we noted particularly dental fluorosis, bone involvement and neurological damage 144 [11-13].

145 The risk score was very significant in 7 cases (11% of our study population). This is a quit 146 important number for a study population of 60 people. This tells us that special attention should be 147 paid about this issue.

148 Presently, the National Research Council (NRC of USA) recommends the Environmental Protection Agency (USEPA) to lower the permitted limit. This was due to a large body of evidence linking 149 fluoride ingestion with increased rates of bone fracture, joint pain (arthritis) and tooth damage (dental 150 fluorosis) [12]. To this end, an important point was raised in the NRC of USA report. It tells that since 151 the enamel's function is to protect the inside of the tooth from external attacks, dental fluorosis 152 153 cannot be regarded as a purely aesthetic problem [12]. In fact, Dr. John Colquhoun [14] said that "Common sense tells us that if a poison circulating in the body of a child happens to damage the 154 cells in developing teeth, there are probably other harmful effects". Common sense also tells us that 155 since dental fluorosis affects more than 50% of our study population, corrective action must be taken 156 157 as soon as possible.

158 159

168

175

176

177

160 **4.2. Corrective action plan**

Water is said to be potable when it satisfies a number of characteristics that make it safe for human consumption. Reference standards in this field vary over time and countries and according to the authority in charge in some countries. The concept of "drinkability" varies around the world. It is the result of historical, scientific and local cultural context. It determines the issue of access to water, since good quality of water is essential to the economic and human development.

An action plan must be set up to prevent any impacts that may result from the identified risk (water polluted with fluoride):

On a collective level:

- Submit water to people who have difficulties to access the public drinking water distribution system.
- 171 Raise awareness of Berka's population of the harmful effects of polluted water consumption
 172 (well water) on their health.
- 173 On an individual level:
 174 Support subjects v
 - Support subjects with a very high risk score.
 - A quantitative risk assessment of urinary fluoride concentrations may be practiced by taking measurements.

178 5. CONCLUSION

The health risk assessment of polluted water with fluoride, in the region of Berka was conducted by the method of Kinney. The latter allowed us to objectify risk assessment by prioritizing the health risks and assessing risks. The risk assessment takes into account the risk scores calculated from the product 182 of the occurrence probability score of a harmful result, the exposure frequency and the severity of that 183 consequence or effect. Thus, this will allow us to identify priorities for preventive actions to implement. 184 As a result of this health risk assessment approach to water pollution with fluoride, we were able to 185 show that over 50% of the study population had dental fluorosis and 11% of our population had a very 186 important risk score. 187 An action plan must be set up to prevent any impacts that may result from the identified risk (water 188 polluted with fluoride). 189 190 REFERENCES 191 1.
