## 52 **ABSTRACT**

53 **Aims:** The purpose of this study is to assess and confirm the ameliorative effects of alcohol  
54 consumption on biochemical indices of blood i.e., blood glucose, HbA1c, NO<sub>2</sub>, NO<sub>3</sub>, lipid  
55 profiles, hs-CRP (high sensitive C–Reactive protein) and membrane lipid peroxidation of  
56 diabetics.

57 **Study Design:** Pre-clinical and Biochemical experimental study.

58 **Place and Duration of Study:** Department of Biochemistry, Acharya Nagarjuna University &  
59 Dept. of Biotechnology, K L University, Guntur, A.P and Dept. of Biochemistry, Katuri Medical  
60 College, Katuri Nagar, Guntur, A.P and Dept. of Biochemistry, Sri Krishna Devaraya University,  
61 Anantapur, A.P and Dept. of Basic Sciences, Madanapalle Institute of Technology & Science  
62 (MITS), Post Box No: 14, Angallu (V), Madanapalle, A. P., India, during 2008 – 2013.

63 **Methodology:** The study is conducted on 4 groups (n= 1200) of people of different ages  
64 ranging from 35 to 50 years at community health centers in Prakasam, Warangal, Srikakulam  
65 districts of Andhra Pradesh, India. The first group consists of type-II diabetic patients who have  
66 been consuming alcohol (arithmetic mean ranging from 14.16 to 31.61ml/day) moderately for  
67 the past 3 to 10 years. The second group consists of non-diabetic, moderately alcohol  
68 consuming healthy individuals. The third group consists of patients who are type-II diabetics  
69 (who do not drink) taking medical treatment for minimum period of 1 year. The fourth group  
70 consists of non-drinking, non-diabetic healthy individuals. Relationships of alcohol intake with  
71 lipid profile, hs-CRP and HBA1c are compared among the three groups.

72 **Results:** In lipid profile analysis of moderately drinking diabetic group, the HDL levels are found  
73 to be higher while the remaining factors such as total cholesterol, LDL, VLDL ( $P<0.05$ ),  
74 triglycerides ( $P<0.01$ ) and membrane lipid peroxidation are significantly lower. Fasting serum  
75 glucose levels are lowered, while serum nitrites and nitrates are found to be significantly higher.  
76 These differences are not found in abstainers group and Diabetic group who do not drink.

77 **Conclusion:** Moderate consumption of alcohol in diabetic individuals is found to have an  
78 inverse association with the risky factors like LDL cholesterol, Triglycerides, etc. that are the  
79 etiological factors for some of the sequelae of diabetes mellitus i.e., coronary heart diseases,  
80 Retinopathy, etc. and has a direct association with the positive factors such as HDL and nitric  
81 oxide production. Experimental results are very significant and indicate that moderate  
82 consumption of alcohol has ameliorative effects on diabetics.

83  
84 Keywords: diabetics, moderate drinkers, lipid profiles, Nitrites & Nitrates, HDL and HbA1c.

85  
86

## 87 **1. INTRODUCTION**

88

89 Diabetes is a disorder where the body does not produce insulin or does not properly use insulin.  
90 According to recent estimates, approximately 285 million people worldwide (6.6%) are suffering from  
91 diabetes and this number is expected to rise by 438 million people (7.8%) of the adult population by 2030  
92 [1, 2, 3, 4]. Glucose is derived from all sorts of foods that we consume. After every meal a large part of  
93 our food is converted into glucose, thereby increasing the blood glucose levels. The Insulin, a hormone  
94 secreted by pancreas carries the blood glucose to cells that need energy [5, 6]. In diabetic individuals,  
95 insulin is either not produced or not utilized properly, and hence the glucose remains in the blood causing  
96 the condition “Diabetes” [7, 8]. Today, diabetes mellitus type 2 is posing several challenges to the  
97 medical field due to its association with multiple physiological complications such as Cardiovascular  
98 complications, Microangiopathy, Neuropathy, Nephropathy, Retinopathy, Dermatopathy, etc [9]. Currently

99 oral hypoglycaemic agents used for the treatment of Type 2 diabetes include insulin secretagogues like  
100 sulfonylureas and metformin. Metformin acts through multiple poorly characterized mechanisms, one of  
101 which inhibits de novo glucose synthesis via indirect AMP-activated protein kinase (AMPK) activation,  
102 potentially following partial mitochondrial complex I inhibition in the liver [10]. Recently, the focus has  
103 been shifted towards the use of moderate alcohol to treat Type 2 diabetes. Alcohol consumption is  
104 increasing day by day, not only in Asian countries but also throughout the world. Alcohol is a globally  
105 abused psycho-active drug with its adverse side effects but it has also some important beneficial effects  
106 like relaxation of mental tension, vasodilatory effect on human health [11]. Excessive consumption of  
107 alcohol has definite adverse effect on human health. Several studies have shown that people with the  
108 habit of excessive drinking of ethanol are found to have fatty liver [12], cognitive disorders and permanent  
109 irreversible liver damage. On the other hand, it is also shown that moderate consumption of alcohol has  
110 beneficial health effects [13, 14, 15]. The concept of moderate consumption of ethanol (beverage alcohol)  
111 has evolved over time from considering the level of intake to be non-intoxicating and non-injurious.  
112 Moderate drinking can be defined as the level corresponding to the lowest overall rate of morbidity or  
113 mortality in a population [16].

114  
115 Therefore, in our study we have evaluated the ameliorative effects of alcohol consumption on biochemical  
116 indices on human diabetic volunteers. The main criteria to study on these groups is the 'diabetes' a  
117 debilitating multifactorial disorder, is keep on increasing in Southern parts of India from the past two  
118 decades that coincide with intake of alcohol from last twenty years (*unpublished data*). We wanted to  
119 study the relationship between alcohol intake with diabetes and their ameliorative effects among the  
120 groups in these particular regions of Andhra Pradesh. Our results show that moderate alcohol  
121 consumption enhanced the levels of HDL by lowering LDL and total triglycerides pools. Moreover,  
122 enhanced levels of serum NO<sub>2</sub> and NO<sub>3</sub> are noticed in moderate alcohol drinking diabetic as well as non-  
123 diabetic volunteers.

## 124 125 **2. MATERIALS AND METHODS**

### 126 127 **2.1 Subjects for study**

128  
129 The study is conducted on 4 groups of people of different ages ranging from 35 to 50 years at community  
130 health centers in Prakasam, Warangal, Srikakulam Districts of Andhra Pradesh, India. The first group  
131 consists of type-II diabetic patients who have been consuming alcohol moderately for the past 3 to 10  
132 years. This group is named as MDD (Moderate Drinking Diabetics). The second group consists of non-  
133 diabetic moderately drinking healthy individuals called MDND (Moderate drinking non-diabetes). The third  
134 group consists of non-drinking type-II diabetic patients who have been under medical treatment for a  
135 minimum period of 1 year. This group is named as NDD (Non-Drinking Diabetics). The fourth group  
136 consists of non-drinking, non-diabetic healthy individuals. This group is Abstainers (Table 1). All

137 volunteers involved in the present study are well informed and their consent is obtained and size of the  
138 each group is 1200 keeping a total of 4800 individuals. All the members of the above groups are free from  
139 Coronary Heart Diseases (CHD), Cerebro Vascular Diseases (CVD) and Cancer.

140

## 141 **2.2 Determination of fasting blood glucose**

142 Blood samples from every individual are collected into EDTA containing tubes by venipuncture. Levels of  
143 glucose in serum are estimated using monozyyme diagnostic kit, which is based on the GOD-POD method  
144 [17]. In brief, glucose is oxidized by the enzyme glucose oxidase to give D-gluconic acid and hydrogen  
145 peroxide. Hydrogen peroxide in presence of enzyme peroxidase oxidizes phenol, which combines with  
146 amino antipyrine dye to produce a red coloured quinoneimine which is measured at 505 nm against water  
147 blank.

148

## 149 **2.3 Determination of serum triglycerides**

150 Serum triglycerides are estimated using Qualigens diagnostic kit which is based on the method [18]. In  
151 brief, triglycerides in the sample are hydrolyzed by microbial lipase to glycerol and free fatty acids.  
152 Glycerol is further phosphorylated to glycerol 3-phosphate and is oxidized to dihydroxy acetone  
153 phosphate. Liberated hydrogen peroxide reacts with 4-amino anti pyrine and 3, 5 dichloro 2-hydroxy  
154 benzene sulphonic acid. Absorbance of quinoneimine and colour dye formed is proportional to the  
155 concentration of triglycerides.

156

## 157 **2.4 Determination of Serum Total Cholesterol**

158 Serum total cholesterol is estimated by the enzymatic kit method [19]. In brief 0.01ml of serum is added to  
159 1ml of freshly reconstituted enzyme reagent, mixed well and incubated at 37<sup>0</sup>C for 5 minutes. After  
160 incubation, absorbance is measured at 505nm against blank. Simultaneously standards are run along  
161 with the test under similar conditions.

162

## 163 **2.5 Determination of HDL and LDL -Cholesterol**

164 Serum HDL-Cholesterol is estimated by autozyyme diagnostic kit method. 0.5ml of HDL precipitant reagent  
165 (Phosphotungstic acid 2.4 mmol/L and Magnesium Chloride 40m mol/L) is added to 0.5ml of serum,  
166 mixed thoroughly, centrifuged at 4,000 rpm for 10min to obtain a clear supernatant. 1ml of working  
167 standard (enzymatic cholesterol reagent of autozyyme diagnostic kit) is added to 0.05ml of supernatant,  
168 incubated for 10min at 37<sup>0</sup>C and the development of color is read at 510 nm against a blank. A standard  
169 is maintained simultaneously. LDL and VLDL cholesterol are calculated using the formula of [20].

170

## 171 **2.6 Determination of CRP protein in serum**

172 Cholestech LDX hs-CRP is an *in vitro* diagnostic test for the quantitative determination of hs – CRP (high  
173 sensitive C–Reactive protein) in whole blood or serum [26]. Finger stick samples are collected using a  
174 Cholestech LDX 50 µl capillary tube. The cassette is placed into the drawer of the analyzer immediately  
175 after dispensing the sample into the well. After pressing run, hs-CRP results are displayed in 6 minutes

176 (results are displayed in 4 minutes for serum of serum sample). It is found that Hematocrit levels between  
177 30% and 55% do not affect the results.

## 178 179 **2.7 Determination of total blood Nitrite and Nitrate**

180 Nitrites and Nitrates are estimated in the serum samples of the subjects [22, 23]. Serum samples are  
181 deproteinated by adding 30% ZnSO<sub>4</sub> followed by centrifugation at 10,000 rpm for 5 minutes. Then, 1ml of  
182 serum supernatant is mixed with 1ml Greiss reagent (1g/lit sulfanilamide, 25g/lit phosphoric acid and  
183 0.1gm/lit N-(1-Naphthyl) ethylene diamine dihydro chloride) and incubated at room temperature for 10  
184 minutes for color development. The absorbance is measured at 545 nm in Elico Spectrophotometer  
185 against blank.

## 186 **2.8 Statistical Analysis**

187 All the values of body weight, fasting blood sugar, and biochemical estimations are expressed as mean ±  
188 standard deviation (S.D). Differences of mean values are assessed by using large sample Normal test z  
189 follows N (0, 1) because the sample size is 1200 (>30).

190 **Methodology:** Null hypothesis ( $H_0$ ) → There are no significant difference between MDD and NDD,  
191 MDND and Abstainers.

192 **Alternative hypothesis ( $H_1$ ):** Moderate drinking alcohol is beneficial in both the cases Diabetic as well  
193 as non-diabetic (One tailed test)

194 Under null hypotheses the test statistic is given by

$$195 \quad Z = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}} \sim N(0,1)$$

196 If calculated value of  $Z \leq Z_\alpha$  (Critical value) we accept  $H_0$  at  $\alpha\%$  level of significance, otherwise we  
197 reject  $H_0$  and conclusions can be drawn accordingly.

## 198 199 **3. RESULTS AND DISCUSSION**

200 Diabetes is a complex metabolic disorder and several factors such as environmental and life style factors  
201 have shown to be responsible for the origin and development of diabetes mellitus. Although diabetes is as  
202 old as human life on earth, researchers are yet to find out a therapeutic factor with less diabetic  
203 complications. In this paper, the authors explore the possible action of alcohol intake and diabetic control  
204 by measuring several biochemical indices in the blood serum of diabetics. However, the alcohol content  
205 in different drinks i.e., wine, brandy, whisky and other beverages varies considerably [24]. Therefore, a  
206 questionnaire has been prepared to know the type of drink consumed by MDD and MDND, which are  
207 shown in table 2. Based on that we calculated the arithmetic mean consumption of ethanol per day drunk  
208 by MDD and MDND, which ranges from 14.16 ml to 31.85 ml. Evaluation of the blood samples shows  
209 that moderate consumption of alcohol positively influences the indices of blood parameters of diabetics as  
210 well as non-diabetics i.e., hs-CRP protein, fasting blood glucose, HbA1c, total blood Nitrite and Nitrate,

211 total cholesterol, HDL, LDL, VLDL, Triglycerides and membrane lipid peroxidation and hence it is useful  
212 to ameliorate the deleterious effects of diabetes mellitus.

213  
214 **People who have habit of drinking alcohol (either heavy or moderate) have their own choice of drinking**  
215 **their selected brand. However, the alcohol content in different drinks i.e., wine, brandy, whisky and other**  
216 **beverages varies considerably [24]. Therefore, it is worthwhile to know the impact of alcohol on mucosal**  
217 **surface hence lipid peroxidation has great importance. In our experiments results showed that membrane**  
218 **lipid peroxidation is greatly lowered in MDD than NDD. In MDND the lipid peroxidation is higher than**  
219 **Abstainers due to the impact of alcohol on membrane. This data clearly shows that the ameliorative**  
220 **action of moderate alcohol on diabetic individuals than non-diabetic individuals. Similar results are also**  
221 **observed in hs-CRP and HbA1c levels (Table 3).** In lipid profile analysis, only HDL levels are increased in  
222 MDD and MDND than NDD while remaining factors such as total cholesterol, LDL, VLDL ( $P<0.05$ ),  
223 membrane lipid peroxidation and triglycerides ( $P<0.01$ ) are significantly reduced (Table 4). Both the study  
224 groups (MDD & NDD) are compared with the MDND and abstainers. These results on lipid profile due to  
225 the impact of alcohol consumption are supported by several authors who conducted experiments on  
226 different animals including human beings [25]. Similar experiments are conducted on men with and  
227 without diabetes and a positive association between alcohol intake and blood pressure, triglycerides and  
228 HDL cholesterol is found [26]. Some researchers may still have a doubt whether excessive consumption  
229 of alcohol may result in obesity. But, this ambiguity is already resolved by [27] who observed that  
230 drinkers, despite their higher alcohol intake, are no more obese than nondrinkers. Their observations  
231 strongly complement the explanation of present study especially referring the mean BMI in MDD and  
232 MDND (Table 1). **Several reports are already noticed that drinking of alcohol once or twice a week will**  
233 **reduce the body weight while every day drinking gain more weight. This is due to the stimulatory effect of**  
234 **alcohol on metabolism. In our experiments it is noticed that BMI is less in MDD compared with NDD**  
235 **because of moderate drinking. While comparing MDD and MDND, surprisingly BMI is higher in MDD than**  
236 **MDND; this is due to the impact of diabetes on body. In MDND, moderate alcohol consumption gives**  
237 **very significant lowering impact on BMI. However, our earlier reports revealed that those who are drinking**  
238 **either moderately or heavily have an habit of eating too much fatty foods during the drinking in most of the**  
239 **cases, causes display of higher BMI in all such individuals (unpublished data). Therefore, we clearly seen**  
240 **this fact when compared the BMI of MDND with Abstainers.**

241  
242 The levels of serum Nitrites and Nitrates are found to be increased in MDD and MDND as compared to  
243 NDD ( $P<0.05$ ) (table 3). Earlier studies revealed that moderate alcohol consumption might have induced  
244 an increase in insulin secretion, sensitivity to insulin, increased serum nitrites and nitrates levels in MDD  
245 and MDND than NDD. Relationship between serum Nitric Oxide (NO) production, lipid abnormalities and  
246 oxidative stress in diabetes are noticed earlier [28]. Many reports strongly support that diabetes mellitus  
247 is associated with decreased Nitric Oxide production from endothelial cells and decreased levels of serum  
248  $\text{NO}_2$  and  $\text{NO}_3$  [28, 29, 30, 31]. Moderate alcohol consumption has been shown to reduce the risk of

249 ischemic heart disease potentially through its effect on specific endothelial-derived compounds. Venkov  
250 et al., [32] have tested the hypothesis that ethanol increases the expression of endothelial Nitric Oxide  
251 Synthase (eNOS) and Nitric Oxide production in Bovine aortic endothelial cells. Luo et al., [33] and  
252 Bequette et al., [34] observed that intake of alcohol has direct influence on wound healing and ascribed  
253 this property of alcohol to increased production of NO which, as a vasodilator, helps in healing the wound.  
254 In fact, alcohol rubbed on skin dilates the blood vessels and produces a mild counter-irritant effect. In the  
255 general practice of public, whenever a small cut/injury appears on the body, people pour a few drops of  
256 alcohol on the injured part and the wound gets healed subsequently. Other reports also strongly suggest  
257 that increased production of nitric oxide in alcoholic diabetics reduces the serum glucose levels, oxidative  
258 stress, lipid and lipoprotein abnormalities [18, 35, 36, 37, 38, 39]. The etiological factor for most of the  
259 sequelae of diabetes mellitus of type I or II i.e., Retinopathy, Nephropathy, Cardio-myopathy,  
260 Polyneuropathy, Neuritis, Erectile and Dysfunction is ischemia due to lowered levels of Nitric Oxide  
261 production. Hence, the authors opine that moderate consumption of alcohol ameliorates the severity of  
262 diabetes mellitus and its sequelae to some extent due to increased nitric oxide synthase protein  
263 expression of one or more isoforms.

264  
265 The moderate consumption of alcohol causes a significantly alleviated in serum glucose ( $P<0.05$ ) and  
266 glycosylated hemoglobin levels in MDD than NDD and MDND than Abstainers as observed earlier  
267 through similar experiments conducted on moderately drinking type-II diabetics [40, 41]. These effects  
268 are purely ameliorated by moderate alcohol consumption. **In contrast to the fasting serum glucose  
269 levels, the serum Nitrite and Nitrate levels are improved in MDD than NDD and in MDND than Abstainers.  
270 According to the Venkov et al., it is revealed that the moderate alcohol consumption enhance the  
271 endothelial Nitric Oxide Synthase (eNOS) and Nitric oxide production (33 & 34). This data is in support to  
272 our results and prove the direct impact of moderate alcohol on diabetic individuals.** Similar results are  
273 reported by [42] conducting experiments on rats where they demonstrated that ethanol acutely exerts  
274 substantial influences on pancreatic microcirculation by evoking a massive redistribution of pancreatic  
275 blood flow from the exocrine into the endocrine part via mechanisms mediated by nitric oxide and vagal  
276 stimuli, augmenting late-phase insulin secretion, and thereby evoking hypoglycemia. This mechanism  
277 seems to involve NO & vagal pathways and is due to the well-known hypoglycemic properties of alcohol  
278 in diabetic patients [43, 44]. A Dutch randomized trial conducted in diabetic teetotallers suggests that a  
279 glass of wine with dinner may improve glucose control, particularly in those with higher HbA1c levels to  
280 begin with. This study, while small, adds to anecdotal evidence and meta-analyses that suggest that wine  
281 may hold specific benefits for diabetics whose cardiovascular benefits have been widely touted  
282 (European Association for the study of Diabetes 2007 meeting, an unpublished report). Experimental  
283 studies on the composition of alcohol stating that the principal ameliorative effect of the alcohol on  
284 diabetics is due to the presence of polyphenols as ingredients (45). However, it is evident that levels of  
285 polyphenolic metabolites that reach the human body are always very low (46). Therefore, it is clear that

286 the moderate alcohol consumption along with polyphenols have involved in the alleviation of glucose  
287 levels in MDD and MDND.

288  
289 Consumption of white and red wines may improve coronary blood flow and improve symptoms in patients  
290 with coronary heart diseases [47]. In our experiments, it is observed that hs-CRP levels in blood serum  
291 are found to be significantly ( $P<0.05$ ) low in MDD and MDND when compared with that of NDD, which  
292 indicates that the probable risk of cardiovascular diseases is low in MDD (Table 3).

293  
294 Glycosylated hemoglobin (Hemoglobin A1c) concentration is a hallmark of glycemic control for prognostic  
295 purpose. HbA1c levels are reported to be in correlation with, not only glycosuria but also serum glucose.  
296 Hormonal profiles and various other factors cannot influence HbA1c concentrations [34]. Our experiments  
297 on HbA1c levels in the MDD, MDND and NDD patients show that lowered levels of blood glucose exist in  
298 MDD and MDND than NDD. These results strongly support our hypothesis that moderate consumption of  
299 alcohol has an ameliorative effect on diabetes mellitus. As the results are very significant, the authors  
300 propose that moderate consumption of alcohol (ranging from 14.16 ml to 31.85 ml per day) is good for the  
301 health of the diabetics. This range is very much below the safer range i.e., 30 to 40 ml of ethanol  
302 consumption/day as advised by the UK government (International center for Alcohol Policies, USA).

303  
304 **4. CONCLUSION:**  
305 Moderate consumption of alcohol in diabetic individuals is found to have an inverse association with the  
306 risky factors like LDL cholesterol, Triglycerides, etc. that are the etiological factors for some of the  
307 sequelae of diabetes mellitus i.e., coronary heart diseases, Retinopathy, etc. and has a direct association  
308 with the positive factors such as HDL and nitric oxide production. Experimental results are very significant  
309 and indicate that moderate consumption of alcohol has ameliorative effects on diabetics.

## TABLES & LEGENDS

**Table -1: Profile of subject groups with and without diabetes**

Variables	Alcohol consumption category			
	Moderate drinking Diabetes (MDD)	Non-drinking Diabetes (NDD)	Moderate Drinking non-Diabetes (MDND)	Abstainers
Gender	Male	Male	Male	Male
Number	1200	1200	1200	1200
Age (Years)	52.2 ± 7.8	52.2 ± 7.8	52.2 ± 7.8	52.2 ± 7.8
Body mass index (Kg/m <sup>2</sup> )	25.28 ± 3.27*	28.32 ± 5.21	25.61 ± 0.06 <sup>†</sup>	23.32 ± 2.39
Waist Circumference (Inches)	85.9 ± 13.2*	89.4 ± 15.2	89.3 ± 8.2 <sup>†</sup>	84.3 ± 10.2
Daily consumption of moderate alcohol (≥22 and ≤44 g ethanol/day)	All*	Nil	All <sup>†</sup>	Nil
Smokers (%)	52.4	42.5	60.5	Nil
Systolic blood pressure (mmHg)	132.4 ± 17.2*	138.4 ± 17.8	132.65 ± 2.7 <sup>†</sup>	130.3 ± 16.7
Diastolic blood pressure (mmHg)	81.4 ± 12.1*	82.4 ± 13.1	86.4 ± 5.4 <sup>†</sup>	80.4 ± 11.1
Therapy for diabetes (%)	58.7*	59.3	Nil	Nil
Therapy for hypertension (%)	42.2*	35.8	15.8	8.0
Therapy for dyslipidemia (%)	15.9*	23.7	10.6	8.2

437 Mean with standard deviation or percentages of variables were compared between the non-diabetic and  
438 diabetic with drinkers and non-drinkers.

439 <sup>†</sup>Dose size is 13.0 to 40.0 % ABV (Percent Alcohol by Volume from typical beverage).

440 \* Significant variation observed between MDD and NDD (Calculated Z>1.645)

441 <sup>†</sup> Significant variation observed between MDND and Abstainers (Calculated Z>1.645)

442

443  
444  
445

**Table - 2:** Calculation of ethanol content in drinks consumed by MDD.

S. No.	Type of Drink	ABV* ( %)	Daily consumption of drink ** (in ml)	Daily consumption of ethanol ***(in ml)
1	Wine	13.5	105.00	14.16
2	Brandy	40	77.65	26.76
3	Rum	37.5	80.00	30.00
4	Gin	40	71.25	28.50
5	Whisky	40	79.62	31.85
6	Cheap Liquor	40	79.02	31.61

446  
447  
448

\* Typical Alcohol by Volume; \*\* Arithmetic mean alcohol consumption by MDD in a week time;  
\*\*\* Arithmetic mean alcohol consumed equivalent to ethanol per week (i.e., 220 ml)

449  
450  
451  
452  
453

**TABLE-3:** Impact of alcohol on biochemical parameters of serum and erythrocyte membrane in different experimental groups

S. No.	Biochemical Parameter	Alcohol consumption category			
		Moderate drinking Diabetes (MDD)*	Non-drinking Diabetes (NDD)	Moderate Drinking non-Diabetes (MDND) **	Abstainers
1	Fasting serum glucose (mg / dl)	130 ± 4.3	180 ± 7.0	94 ± 2.2	72± 2.3
2	hs-CRP (mg/L)	2.54 ± 0.05	3.12 ± 0.03	2.37 ± 0.03	1.3± 0.06
3	HbA1c <sup>†</sup>	9.5 ± 2.3	11.4 ± 2.2	6.55 ± 0.05	6.5± 1.0
4	Serum Nitrites (µ moles/L)	2.5 ± 0.04	2.3 ± 0.03	2.33 ± 1.03	1.6± 1.0
5	Serum Nitrates (µ moles/L)	24.5 ± 0.4	22.7 ± 0.5	24.6 ± 6.7	23.1 ± 8.9
6	Membrane Lipid peroxidation (pmol of MDA) <sup>††</sup>	4.961 ± 1.15	8.304 ± 1.026	5.542 ± 1.026	3.20 ± 0.15

454  
455  
456  
457  
458  
459  
460

<sup>†</sup>Determined using Glycated hemoglobin assay kit recommended by the American diabetes association (ADA) and is expressed as a percentage (%) of the hemoglobin

<sup>††</sup>Malonaldehyde formed / mg membrane protein

\* Significant variation observed between MDD and NDD (Calculated Z>1.645)

\*\*Significant variation observed between MDND and Abstainers (Calculated Z>1.645)

461 **TABLE-4:** Variation in the lipid profiles of diabetic volunteers with and without drinking  
 462

S. No.	Parameter ( mg / dl)	Alcohol consumption category <sup>†</sup>			
		Moderate drinking diabetes (MDD)*	Non-drinking Diabetes group (NDD)	Moderate Drinking non- Diabetes (MDND)**	Abstainers
1	Total Cholesterol	220 ± 8.4	265 ± 7.8	188 ± 05	198 ± 8
2	Triglycerides	170 ± 8.5	250 ± 5.3	152 ± 07	142 ± 29
3	HDL	82 ± 5.1	53 ± 3.7	64 ± 3.3	42 ± 1.8
4	LDL	51 ± 3.6	59 ± 4.0	61 ± 2.8	60 ± 10
5	VLDL	35 ± 3.1	48 ± 3.6	32 ± 1.6	38 ± 2.0

463 <sup>†</sup>Values (n=1200) represented as mean values ± S.D.

464 \* Significant variation observed between MDD and NDD (Calculated Z>1.645)

465 \*\*Significant variation observed between MDND and Abstainers (Calculated Z>1.645)
