2

## ABSTRACT

5 6

**Aims**: To evaluate eleven medicinal plants as natural sources that possesses strong antidermatophytic, antibacterial, anticandidal and antioxidant substances with potential applications in therapeutics and food industry.

Place and Duration of Study: Sample: Biodiversity and Environmental Research Center, BERC, between December 2013 and April 2014.

**Methodology**: Twenty methanolic extracts were prepared from different parts of eleven plants used in traditional medicine in Palestine. The plants extracts were screened for total flavonoid and phenolic content using standard procedures. The crude extract was screened against six bacterial strains (*Staphylococcus aureus, Proteus vulgaris, Pseudomonas aeruginosa, Salmonella typhi, Escherichia coli,* and *Klebsiella pneumoniae*), 5 *Candida albicans* strains, and 2 dermatophytes (*Microsporum canis,* and *Trichophyton rubrum*). The antioxidant potential of the crude extract was also determined using the DPPH assay.

**Results**: The best free-radical scavenging was for the leaves of *Epilobium hirsutum* (IC50=33  $\mu$ g/ml) and *Rhus coriaria* (49  $\mu$ g/ml) compared with BHA standard (9  $\mu$ g/ml). The highest value of phenolics was in *Rhus coriaria* fruits (14.7 mg/g dried plant material) and for flavonoids was for *Epilopium hirsutum* leaves (1.14 mg/g). The most active extracts against bacteria was the *Rhus coriaria* leaves (% inhibition, 66.2 %) compared with gentamicin (100%) and against *Candida* were leaves of *Rhus coriaria* (100 %) and *Epilopium hirsutum* (72.4 %) compared with amphotericin B (100 %). On the other hand fruits *of Rhus coriaria* showed the best antifungal activity against all the tested dermatophytes, 97% and 86% inhibition were achieved against *Microsporum canis* and *Trichophyton rubrum*, respectively.

**Conclusion**: Our results introduce a natural source (*Rhus coriaria* and *Epilobium hirsutum*) that possesses strong antidermatophytic, antibacterial, anticandidal and antioxidant substances with potential applications in therapeutics and food industry.

### 11 1. INTRODUCTION

12 Herbal medicine is common in developing countries, and is practiced by a large proportion of the

13 population for the treatment of various diseases. In Palestine, many medicinal plants used in folk

medicine against various diseases have been documented with the ethnobotanical field surveys carried out in the area, for the treatment of various diseases including cancer, injuries, and chronic diseases [1-6]. Many medicinal plants and their parts have been shown to have medicinal value and can be used to prevent, alleviate, or cure several human diseases. Plants contain various phytochemicals which can play an important role in reducing occurrences of many diseases by boosting up various organ functions of the human body [7,8].

20 A large number of medicinal plants have been investigated for their biological activities all over the world. 21 Numerous scientific studies were designed for plant species used as folk remedies. Most of research results are in good agreement with the traditional utilization of the tested plants [9]. It is believed that folk 22 23 remedies are major sources of new materials for antimicrobial and antioxidant drugs [10]. Antioxidants 24 have many potential applications, especially in relation to human health, both in terms of prevention of disease and therapy [11]. Antioxidants are considered to play an effective role in inhibiting and 25 scavenging free radicals, and are also of particular importance because they might serve as leads for the 26 development of novel drugs. The most oppmonly used synthetic antioxidants have side effects such as 27 liver damage and carcinogenesis [12]. Natural antioxidants either in the form of raw extracts on 28 29 chemical constituents are very effective to prevent the destructive processes caused by stress [13]. In this 30 context, antioxidants especially derived from natural sources such as medicinal plants and herbal drugs 31 require special attention.

32 Drug resistance to human pathogenic bacteria and fungi has been commonly reported from all over the 33 world [14], thus the increasing prevalence of multidrug resistant strains of pathogenic microorganisms and the recent appearance of strains with reduced susceptibility to antibiotics raises the need to search 34 for new sources of antimicrobial agents [15]. Human infections, particularly those involving skin and 35 mucosal surfaces constitute a serious problem. Fungal infections have increased at an alarming rate in 36 37 the last 20 years, mainly among immune compromised individuals [16]. New data indicate that the relative proportions of organisms causing nosocomial bloodstream infections have changed over the last decade, 38 39 with Candida species now firmly established as one of the most frequent agents. Candidemia is not only 40 associated with a high mortality but also extends the length of the hospital stay and increases the costs of 41 medical care. Among human gastrointestinal tract isolates, 50-70% of total yeast isolates were identified 42 as Candida alpicans [17,18]. Therefore the discovery of antioxidant, antimicrobial and antifungal agents from plants based on the evaluation of traditional plant extracts is a very important research topic. 43

In this study 20 methanol extracts prepared from different parts of 11 Palestinian plants used in Traditional Arabic Palestinian herbal medicine (TAPHM) for the treatment of various ailments were evaluated for their antioxidant activity using DPPH, total flavonoid and phenolic compounds content, and the biological activity of these plants extracts against bacteria, Candida and dermatophytes.

48

# 49 2. MATERIAL AND METHODS

### 50 2.1. Chemicals

51 2,2–Diphenyl-2-picrylhydrazyl (DPPH), buthylated hydroxyanisol (BHA), and α-tocopherol were 52 purchased from Sigma, (Sigma, Aldrich GmbH, Sternheim, Germany); pyrocatechol, quercetin, Folin-53 ciocalteu's reagent (FCR), peptone, agar, dextrose, Muller–Hinton agar (Fluka), sabouraud dextrose agar 54 (Difco), dextrose, agar, gentamicin, amphotericin B and econocole, were purchased from Merck 55 (Darmstat, Germany). Sodium carbonate, ethanol, methanol and all other chemicals and reagents were of 56 analytical grade.

### 57 2.2. Plant Material

58 Medicinal plant species screened in this study were collected from different regions of Palestine between 59 April and August 2013. They were identified by Prof. M. S. Ali-Shteveh from the Biodiversity and 60 Environmental Research Center, BERC, Til Village, Nablus (Table 1). Voucher specimens are deposited 61 in the Herbarium of BERC.

### 62 2.3. Extracts Preparation

Fresh plant parts were ground using a Molenix (Mooele Depose type 241) for a minute and the resulting powder was lyophilized and stored in at - 80 °C for future use. Fifty grams of the lyophilized plant meterial were extracted by homogenization with 80 % methanol (10 ml g–1), for 72 h then filtrated through Whatman No. 4 filter paper. The solvent was removed at 45 °C under reduced pressure followed by freeze drying using freeze dryer (Alpha 1-2 LD plus). The crude extracts were stored at –20 °C for further use.

### 68 2.4. Phytochemical Screening

# 20 69 2.4.1. Determination of total phenolic contents

70 The amount of total phenolics in extracts was determined with the Folin-Circulateu reagent using the method of Dicko et al [19] with adaptation of the method to the 96 well-plate. Gallic acid was used as a 71 standard and the total phenolics were everessed as mg/g gallic acid equivalents (GAE). Concentrations 72 73 of 2.4, 4.87, 9.75, 19.5, 39, 78, 156 µg/ml of gallic acid were prepared in methanol. Concentration of 2.5 mg/ml of plant extract was also prepared in methanol and 20µl of each sample were introduzed into the 74 75 wells and mixed with 100 µl of 0.2 N Folin- Ciocalteu reagent, the plate was incubated 5 min at room temperature followed by the addition of 80µl of 7.5% sodium carbonate. The micro-well plate was 76 covered to protect from light and allowed to stand for 30 minutes at room temperature before the 77 absorbance was read at 735 nm using a multi-well plate reader Biotek, USA. All determinations were 78 79 performed in triplicate. The Folin-Ciocalteu reagent being sensitive to reducing compounds including 80 polyphenols is producing a blue color upon reaction which can be measured spectrophotometerically [20].

### 85 2.4.2. Determination of total flavonoids contents

The total flavonoids content of each plant extract was estimated by aluminium chloride colorimetric assay 86 described by Chatatikun & Chiabchalard [21]. The reaction was carried out by mixing 25µl of the plant 87 extract (2.5mg/ml) or standard solution of quercitin (400, 200, 100, 50, 25, 12.5, 6.1, 3.6 µg/ml) in 80 % 88 methanol, with 1941 of AICI3 solution (10%), followed by the addition of 175 µl of 100 % methanol. 89 90 Methanol (80 %) was used as reagent blank. Finally 10 µl of 1M sodium acetate was added to the mixture in a 96 well plate. The reaction was mixed and incubated for 40 minutes at room temperature protected 91 from light. The absorbance was measured at 415 nm with a Micro plate Reader (Biotek, USA.). Total 92 93 flavonoid contents in the plants extracts were expressed as mg Quercitin Equivalents (QE) per gram of 94 dry plant material. All samples were analyzed in triplicates.

### 95 2.5. Determination of Antioxidant Activity Using DPPH Free Radical Scavenging

Free radical scavenging activity of the extracts was determined using the free radical 1,1-diphenly-2-96 picrylhydrazyl-hydrate (DPPH). The effect of the plant extracts on DPPH radical was performed as 97 98 described by Liyana-Pathirang and Shahidi [22] with minor modification. Briefly, 25µl of each plant extract (ranging from 0 to 10 mg/ml) or standard solution of ascorbic acid, BHA and Gallic acid (ranging 99 100 from 0.0024 mg/ml to 0.156 mg/ml) were added to 175 µl of 0.0042% DPPH methanol solution in 96 micro-well plate. Appropriate blanks were prepared using the solvent only in addition to the same amount 101 102 of DPPH reagent to exercome any inherent solvent activity. All reaction mixtures were mixed well and incubated in the dark for 30 minutes at room temperature. The absorbance was measured at 517 nm with 103 104 a Microplate Reader (Biotek, USA). Experiments were done in triplicates. The ability to scavenge DPPH 105 radical was calculated using the following equation:

106  $RSA = [(Ac-As)/Ac] \times 100\%$ 

There RSA is the percentage of tree radical scavenging activity, Ac is the absorbance of blank, As is the 107 absorbance of sample. The concentration of sample required to scavenge 50% of the DPPH free radical 108

(IC50) was determined from the curve of % of inhibitions plotted against the respective concentration. 109 35

The antioxidant activity index (AAI) was then calculated as follows: 110

35 AAI=[DPPH] (μg ml-1)/IC50 (μg ml-1) 111

112 Where [DPPH] is final DPPH concentration.

#### 113 2.6. Microbiological Studies

Antimicrobial activity of different plants extracts was evaluated by agar well diffusion method and 114

115 minimum inhibitory concentration MIC. Microorganisms used in this study are listed in table 2.

### 118 2.6.1. Well-diffusion method

119 Antibacterial and anticandidal activities of the selected plants extracts were assessed using the agar welldiffusion method [23]. Muller-Hinton and Muller-Hinton supplemented with glucose-methylene blue plates 120 were used for entibacterial and anticandidal susceptibility tests, respectively. An inoculum of 18 hour old -121 broth culture (turbidity adjusted to approximately 108 CFU/ml of bacterium and candida, compared with 122 0.5 McFarland standards) [24] of respective bacterial and candida strain was uniformly spread on these 123 media in separate plates [25]. Well  $\frac{6}{40}$  mm diameter) were created in these plates, and 50 µl of plant 124 stracts (100 mg/ml) were pipetted into the wells and allowed to diffuse at room temperature for 30 min. 125 126 Plates were incubated and 7 °C for 18-24 h [26]. The zone of inhibition for each extract was measured and 127 expressed in mm [25]. The activity index (AI) and Percent Inhibition (PI) were calculated for all extracts 128 obtained at a concentration of 100 mg/ml using the following formula:

129 AI = 130 Z

Mean zone of inhibition of each extract Zone of inhibition obtained for standard antibiotic

131 PI = AI X100

All the experiments were done in triplicates. Gentamicin (10mg/mL) and amphotericin B (32µg/mL) were
 used as positive controls for bacteria and candida, respectively.

### 134 2.6.2. Broth Micro-dilution test

Broth micro-dilution mas performed following the CLSI M27-A2 method [27] Plant extracts were 135 dissolved in methanol and the correct volume was pippeted in the first micro-plate well with Muller-Hinton 136 137 media (pH 7.2), for the concentration of each plant extract to be 5 mg/mL in that well. The cell suspension 138 was prepared in 0.85% saline, with an optical density equivalent to 0.5 McFarland standards, and diluted 139 1:100 in the media to obtain a final concentration of 1 x 104 to 5 x 104 colony-forming units per milliliter 140 (CFU/mL). This suspension was inoculated in each well of a micro-dilution plate previously prepared 141 with the plant extracts to give concentrations from 5 mg/mL down to 0.039 mg/mL [28]. The plates 142 were incubated with agitation at 37 °C for 24 h for all species. The control drugs were gentamicin for 143 bacteria strains, and amphotericin B for Candida, respectively. Concentrations of controls were anged 144 from 250-1µg/mL for gentamicin, and from 16.0-0.125µg/mL for amphotericin B. Value of minimum inhibitory concentration (MIC), determined by broth micro- dilution, and was defined as the lowest 145 concentration of the drug completely inhibited the growth of the isolate. For plant extracts, the lowest 146 concentration without visible growth (visually and spectrophotometerically) was defined as MICs 147

### 148 2.6.3. Anti-dermatophyte testing

Plants extracts were tested for their anti-dermatophyte activity against two dermatophyte species using a modified poisoned food technique [29]. Each extract was incorporated in pre-sterilized SDA medium at a

151 concentration of (0.4mg/ml). A mycelial agar disk of 5 mm diameter was cut out of 12 days old culture of the test fungus and inoculated on to the freshly prepared SDA plates. In controls sterile distilled water 152 was used in place of the tested sample as a negative control, while econazole (5 µg/mL) was used as the 153 154 positive control. Three replicate plates were used for each treatment (concentration). The inoculated 155 plates were incubated in the dark at 24°C and the observations were recorded 10 days after incubation. Percentage of mycelial inhibition was calculated using the following formula: 156

157

% mycelial inhibition = (dc- ds / dc) x100%

158 dc: colony diameter of the control, ds: colony diameter of the sample

159 160 161

162

### 3. RESULTS AND DISCUSSION

#### 3.1. Total Phenolic Content 163

164 Polyphenols are secondary metabolites, naturally occurring compounds found largely in plants; they are generally involved in defence against ultraviolet radiation or aggression by pathogens [30]. In food, 165 polyphone is may contribute to the bitterness, astringency, colour, flavour, odour and oxidative stability 166 167 [31]. Epidemiological studies and associated meta-analyses strongly suggested that long term 168 consumption of diets rich in plant polyphenols offered some protection against development of cancers, chronic diseases, osteoporosis and neurodegenerative diseases [32, 33]. Polyphenols and other food 169 170 phenolics are the subject of increasing scientific interest because of their possible beneficial effects on human health in this study TPC was estimated using Folin-Ciocalteu's method. TPC of all extracts was 171 e range of 0.53-14.9 mg GAE/g extract, results showed that TPC differ among different 172 found to be plant parts (Table 1), the highest level of TPC was found in the fruits Rhus coriaria (14.9 mg GAE/g 173 extract), while it was only 0.89 in the plant leaves. Other plants with high TPC were the leaves of 174 175 Epilobium hirsutum (13.46 mg GAE/ g), fruits of Pistacia palaestina (9.7 mg GAE/g), and the leaves of 176 Ephedra aphylla is (8.08 mg GAE/ g).

55 hytochemical analysis of the fruits of Rhus coriaria was conducted recently [34], a total of 211 177 compounds were identified in the epicarp (fruits) of the plant of which 9 compounds were phenolic acids 178 perivatives, and 26 compounds were unusual phenolics conjugated with glycoside-malic acid [34]. Also, 179 several Pistacia species are known to be rich in gallotannins and related phenolic compounds [35, 36]. 180

181 3.2. Total Flavonoid Content

182 Flavonoids comprise the most studied group of polyphenols. More than 4,000 varieties of flavonoids have

- 183 been identified, many of which are responsible for the attractive colours of the flowers, fruits and leaves
- 184 [37].

185 Total flavonoid content was measured using the aluminium chloride colorimetric assay. The total flavonoid content of all extracts ranged between 0.05-1.14 mg QE/g extract (Table 1), the highest level 186 187 of flavonoid content was found in the leaves of Epilopium hirsutum and Pistacia palaestina (1.14 and 188 1.11 respectively), while the lowest flavonoid content was in the underground part extract of Urginea 189 maritima (0.05 mg QE/g extract). Other plants with high levels of flavonoid were leaves of Lycium schweinfurthii (0.82 mg QE/g), and fruits of Ceratonia siliqua (0.789 mg QE/g). The fruit extracts of 190 191 Lycium schweinfurthii and flowers of Echinops adenocaulos had very low levels of flavonoid (0.07 and 192 0.089 mg QE/g, respectively).

193 Methanol plant extracts contained a higher proportion (≥ 50%) of phenolics than flavonoids (Figure 1).

### 194 3.3. Antioxidant Activity

29

In this study, the antioxidant activity of plant extracts were evaluated using DPPH free radical scavenging 195 196 assay. Except for the fruits of Ailanthus altissima, flowers of Alcea setosa, leaves and fruits of Lycium 197 schweinfurthii, and underground parts and fruits of Urginea maritima extracts, all extracts showed DPPH 198 radical scavenging activity. Epilopium hirsutum leaves revealed the highest antioxidant activity with (AAI= 1.298, IC50=33 µg/ml), followed by the extract of Rhus coriaria leaves (AAI= 0.87, IC50=49 µg/ml) (Table 199 1). The activities of leaf extracts varied from (IC<sub>50</sub>=33µg/mI) in Epilopium hirsutum to (IC<sub>50</sub> = 325µg/mI) in 200 Eucalyptus camaldulensis. While the activity of fruit extracts varied from AAI =0.304 in Eucalyptus 201 202 camaldulensis to AAI= 0 in Ailanthus altissima, Lycium schweinfurthii and Urginea maritima. However, the 203 fruits and leaves of Pistacia palaestina which have AAI=0.327 and 0.3, respectively, have been shown by 204 others to possess a high antioxidant activity [38]. 54

In our study, a weak correlation was found between radical scavenging antioxidant activity and total phenolics in plant parts. Interestingly, a few of the collected plant parts with high-antioxidant activity are "low" in phenolic content including the leaves of *Ceratonia siliqua* and *Rhus coriaria*. These plants may serve as sources of antioxidants with new chemotypes.

209

Figure 1 Proportional relation (%) of flavonoids content to phenolic acids in analysed medicinal plants.

### 213 3.4. Antibacterial Activity

42

214 In the present work the antibacterial activity of the twenty methanol extracts of plants parts were 215 evaluated against six bacterial strains, using agar well diffusion and serial micro dilution (MIC) methods. The results of the antibacterial screening test showed that of the twenty extracts tested only seven 216 extracts belonging to 4 plants species showed antibacterial activity (Table 3). The most active plant 217 extract against all bacteria strains was the leaves of Rhus coriaria The percent of inhibition of Rhus 218 219 coriaria leaves extract ranged between 60.9- 76.2 against tested bacteria. However, the leaves of 220 Ailanthus altissima showed moderate antibacterial activity with percent of inhibition of ranged from 41.8 to 55.8. Housever, the fruits of Ailanthus altissima and leaves of Eucalyptus camaldulensis showed the least 221 222 activity. Our results are in accordance with previous studies in which the leaves of Rhus coriaria and Ailanthus altissima have been shown by other researchers to possess high antibacterial activity [5, 39, 223 224 and 40]. Bioactive compounds produced by plants have been found to protect plants against bacteria, 225 fungi and pests [41, 42], thus it is expected that the plants extracts were composed of antibacterial activity. 226

### 229 3.5. Anti-Candida Activity

Of the tested plants, six species out of eleven showed anticandidal activity against all strains (Table 4). The most active plants extracts were the leaves of *Epilobium hirsutum* and *Rhus coriaria*, and the leaves and flowers of *Eucalyptus camaldulensis* with percent of inhibition ranging from 42.4 to 82.6 (Table 4). On the other hand, the fruits of *Ailanthus altissima* and *Ceratonia siliqua* were the least active plant extract with PI ranging between 0.0-36.5, and 0.0-46.1, respectively.

### Table 4 Percent inhibition zone and MIC (mg/mL) of plant extracts against *Candida albicans* strains

Plant (Part)*	BE	RC N43	BEI	RC N72	BE	RC N66	CB	S 6985	CB	<mark>S 939</mark>

### 239 3.6. Antidermatophyte Activity

Many effective synthetic antifungal agents are currently available and have been used for the treatment of dermatophytec infections [9]. However, these antifungal drugs tend to have serious side-effects including toxicity, drug interactions, inadequate pharmacokinetic properties and the development of resistance have been reported [43]. The discovery of natural active components exhibiting a broad spectrum of

antidermatophyte activity may prove useful for the development of antifungal agents. Medicinal plants
 have been a source of wide variety of biologically active compounds for many centuries and used
 extensively as crude material or as pure compounds for treating various disease conditions [44]. Various
 previous researches have been conducted to evaluate the anti-dematophytic activity of plants [9, 45-47].

248 In this study, plant extracts tested have shown considerable antidermatophytic activities at concentration of 0.4 mg/ml against the two tested dermatophytes (M. canis, and T. rubrum) in comparison with the 249 positive control (econazole). The percent of mycelial inhibition at the concentration of 0.4 mg/ml plant 250 251 extract ranged between 13%-97% against Microsporum canis and 7%-86% against Trichophyton rubrum 252 (Figure 2). The most active plants extracts which exhibited more than 50% inhibition against both 253 dermatophytes were the leaves and fruits of Lycium chweinfurthii, Eucalyptus camaldulensis and Rhus 254 coriaria and leaves of Epilopium hirsutum and Ailanthus altissima. Of these extracts the fruits of Rhus coriaria and leaves of Ailanthus altissima revealed the highest antidermatophyte activities with 97 % and 255 74 % mycelial inhibition against (Microsporum canis), respectively, and 86 % and 74% against 256 Trichophyton rubrum (Figure 2). Abdolmaleki et al [48] have shown that methanolic extracts of stem and 257 fruit of sumac had the highest inhibitory activity against Fusarium oxysporum and Phytophthora. 258 259 drechsleri, respectively. While the ethanolic extract of the leaves and methanolic extracts of fruit, leaf and 260 stem had the highest inhibitory activity against Rhizoctonia solani.

261

Plants are rich source of thousands of new useful phytochemicals of great diversity, which have inhibitory 264 effects on all types of microorganisms in vitro. Although more than 600 plants have been reported for their 265 antifungal properties, however a few of them were explored for the active components [44]. In this study 266 leaves have shown to be more active than fruits of the same plant. This might be attributed either to the 267 268 presence of different active chemical compounds or to the different concentrations of these compounds 269 between leaves and fruits. Previous research studies reported the presence of different chemical groups in plant extracts including: phenolics, flavonoids, organic acids, saponins, terpenoids and alkaloids [44, 270 49-51]. The variation between plants extracts activity might be related to the different chemical groups 271 272 and the variation in their concentrations in these plants. The results of the present study might suggest 273 that Rhus coriaria and Eucalyptus camaldulensis are promising and presumably possess compound(s) 274 with chemical properties against dermatophytes.

### 275 4. CONCLUSION

In conclusion, most of plants in this study could be considered as potential sources of natural antioxidant, which can be used as health promoting agents. *Rhus coriaria* extracts have shown to possess promising antibacterial, anticandidal and antidermatophytic activity. Other plants including *Epilobium hirsutum* and *Lycium chweinfurthii* have also shown to possess good anticandidal and antidermatophytic activity, respectively. Our results introduce natural sources that possesses strong antidermatophytic, antibacterial, anticandidal and antioxidant substances with potential applications in therapeutics and food industry.
