RESEARCH PAPER

An integrated soil fertility management decision support tool for coffee: model structure and calibration for Northern Tanzania

.

ABSTRACT

The aim of this study was to develop a simple and quantitative system for coffee yield estimation and nutrient input advice, so as to assist in assessing coffee production as a function of soil and nutrient inputs, and to support decisions at farm level. An earlier model QUEFTS was used as a benchmark. The study was conducted between 2010 and 2013 at TaCRI Lyamungu, with source data taken from Hai and Lushoto districts, Northern Tanzania. Secondary fertilizer trial data were used in model calibration for coffee, which mainly affected Step 1 and 3 while adding two more steps related to balanced nutrition and the economics of integrated soil fertility management (ISFM). Primary soil analytical data and calculated yields on basis of tree number were used for model testing. The result was a new model which we hereby call SAFERNAC (Soil Analysis for Fertility Evaluation and Recommendation on Nutrient Application to Coffee). The model consists of three modules: SOIL, PLANT and INPUT. It consists of two subsequent parts – a baseline approach (no input) for coffee land evaluation; and an integrated soil fertility management (ISFM) approach that involves application of nutrient inputs, for ISFM planning and design of fertilizer experiments. The model was checked for accuracy of the adjusted equations, and found to be capable of reproducing the actual yields by 80-100%. The new model is a useful tool for use in coffee farms.

Key words: Coffee yield model, soil fertility evaluation, Northern Tanzania, nutrient equivalent, nutrient inputs

1. INTRODUCTION

The importance of coffee in the Tanzanian economy is well documented by [1], [2] and [3], among others. Coffee prefers very deep (more than 1.5 m), well drained friable loam and clay soils. Soils with high available water holding capacity, a pH in the range of 5-7 and a high nutrient holding capacity are most suitable [4]. Its average nutrient removal from a 1 ha soil per growing cycle is 135 kg of N, 35 kg of P_2O_5 and 145 kg of K_2O [5]. With a substantial part also getting lost through leaching and downstream flow in the soil, it is essential to replace the mined and lost nutrients by having a well-planned nutrient management programme [6].

In Tanzania, coffee is grown in a wide variety of agro-ecological zones. MARI [7], following the system developed by De Pauw in 1984 and adopted by [8], described the coffee zones as Eastern Plateaus (E12-E15), High plateaus and plains (H1, H2, H3, H5), Volcanoes and rift depressions (N4, N10), Central plateaus (P6) and Western Highlands (W1-W4). These include an altitudinal range of 500 – 3500 masl, and rainfall range of 500 – 3500 mm (mostly over 1000 mm). According to the fundamental growth conditions for coffee [4], [9], [10], water availability in these zones does not pose a serious limitation to coffee, and neither does irradiance or temperature in this tropical Tanzanian situation. This statement, however, does not take into account the imminent threat of climate change. Following [11], this leaves soil condition as a major factor of coffee productivity in the Tanzanian coffee growing zone.

The Northern coffee zone comprises four regions, namely Arusha, Kilimanjaro, Manyara and Tanga. It extends between latitudes $1^{o}42'$ and $5^{o}58'$ S; longitudes $35^{o}25'$ and $38^{o}49'$ E. The coffee growing areas in the zone fit into agro-ecological zones E, H and N, with altitudinal and rainfall ranges as above. The zone is among several that are dedicated exclusively to the production of mild Arabica coffee. Annual coffee production trend for the zone indicates a decline over years. Kilimanjaro, once a giant coffee producer, appears to have suffered most, with annual production decreasing from about 20,000 tons in 1981/82 to less than 5000 tons by 2005/06 [12]. As reflected during the coffee stakeholders’ forum of 2009, soil fertility degradation appears to be the most limiting factor.

Soil fertility is not a distinct property of the soil as such, since many soil properties influence fertility and also influence each other. In its part, soil fertility affects, and is also affected by, the choices that farmers make regarding agricultural production, fertilization, and soil and water conservation regimes, a study of which needs a method for measuring soil fertility. Unfortunately, there is no unique technique [13]. Ultimately, farmers are not interested in the soil properties themselves, but how they affect agricultural production. We therefore need to use models to explain the effects on yields of individual soil properties that are measured by soil sampling. The predicted yield can then be used as an integrative indicator of soil fertility.

One of the important thrusts of Tanzania Coffee Research Institute (TaCRI) is in the area of integrated soil fertility management (ISFM). Considering the diverse environments under which coffee is grown, crop yield and fertilizer modelling becomes of great importance. With many coffee yield modelling attempts so far based on the crop and its physiological processes [14], enough knowledge is now available for devising empirical constants. The work described here therefore focuses on the land and its capacity to support coffee. Its objective was to make a coffee ISFM decision support tool on basis of soil properties, organic and inorganic nutrient inputs; calibrated for the northern coffee zone of Tanzania, with a prospect of scaling up and out.

2. METHODOLOGY

2.1 Background

Efforts to collect and collate the available soil data for purposes of gauging the TaCRI recommendations on soil fertility management started in 2005. Soil data from various places in Kilimanjaro, and results from NPK reference trials at TaCRI Usagara C farm, and fertilizer x tree density trial, Lyamungu were collected. These data were used between 2007 and 2010 in calibrating an earlier developed fertilizer advice model QUEFTS (Quantitative Evaluation of the Fertility of Tropical Soils) [15], [16], [17], [18] and [19], to coffee.

2.1.1 Estimation of physiological nutrient use efficiency (PhE) by coffee

Because in the trials whose data are used in this work crops had not been analyzed, the uptake of nutrients was estimated by dividing the yield by the physiological efficiency (PhE), which relates agronomic yield with nutrient uptake in all crop components [17]. Unfortunately there appears to be no real data on physiological nutrient use efficiency (PhE) by coffee. They were therefore derived from literature on nutrient contents in crop components. The data in Table 1 were collected from [20], [21], [22],and [23], and tuned to the results of TaCRI fertilizer trials. It was assumed that they represent average values. The medium physiological nutrient use efficiency (PhEM) is then found by dividing dry matter production of parchment coffee by gross uptake of nutrients. This results in 1000/70 (=14), 1000/12.5 (=80), 1000/63 (=16) for N, P and K.

Table 1: Rounded indicative values of dry matter production and average nutrient contents in various components of the coffee tree. Dry matter production of pulp and vegetative growth refer to the annual production going together with an annual dry parchment coffee production of one ton.

Component	Dry matter	N	P	K
Parchment coffee	1000	20	2.3	18
Pulp	875	16	6.0	17
Vegetative growth	2000	34	4.2	28
Total DM; Gross uptake	3875	70	12.5	63

2.1.2 Experimental data for model calibration

In the calibration of QUEFTS, we used coffee-based data from two TaCRI's on-station field trials (NPK reference trial; fertilizer x tree density trial) to establish relationships between soil fertility indices and nutrient uptake by coffee. The NPK reference trial had been superimposed on established coffee in 1983. The design was 3^2 factorial with N and K both applied at rates of 80, 160 and 240 kg per ha per year while all units received 60 kg P per ha per year. N and K were applied in three rounds and P in two rounds. Three extra experimental treatments were included as well: N0P0K0, N2P0K2, N2P2K2, where N2 and K2 stand for 160, and P2 for 120, kg ha^{-1} $year^{-1}$. The fertilizer x tree density trial was started at Lyamungu in 1994. It had a split-plot design with tree density (1330, 2660, 3200 and 5000 trees ha^{-1}) as the main treatment, and N application as a sub-treatment (0, 90, 180 and 270 kg N ha^{-1} $year^{-1}$, split-applied in three rounds). Only yields of the best year were used in order to minimize the risk that other factors than soil fertility and NPK had influenced yields. Some soil analytical data of both trials were available (Table 2). Starting with the parameter values of the original QUEFTS model, a trial-and-error procedure was followed until the fit could not be improved further.

Table 2: Soil analytical data for the two on-station trials

Location	SOC g/kg	SON g/kg	P-Bray 1 mg/kg	Exch K mmol/kg	pH water
			NPK reference trial		
Usagara C	18	2.8	67	19	5.7
			Fertilizer x tree density trial		
Trees per ha					

1330	22	2.2	86	22.1	5.7
2660	24	2.4	109	21.1	5.8
3200	21	2.1	65	17.3	5.6
5000	18	1.8	119	18.2	5.3

2.2 Adaptation of QUEFTS to coffee

The first task in adapting QUEFTS to coffee was to review, with the coffee crop in mind, its various steps. These steps deal with the assessment of available nutrients from soil and inputs (A), the calculation of actual uptake (U) of nutrients as a function of the amounts of available nutrients (A), and the estimation of yield (Y) as a function of the nutrients taken up (U). While QUEFTS assessed available nutrients in unfertilized soils [15] and in chemical fertilizers [16], there was a need to consider in Step 1 also organic nutrient inputs as ISFM components.

The calculation of actual uptake of nutrients (Step 2) was adopted as in QUEFTS, as it mainly involved theoretical concepts. The actual uptake of Nutrient 1 (U_1) is calculated twice: $U_{1,2}$ is a function of A_1 and A_2 being the available amounts of Nutrients 1 and 2, $U_{1,3}$ is a function of A_1 and A_3. The lower of $U_{1,2}$ and $U_{1,3}$ is assumed to be the more realistic one in accordance with Liebig's Law of the Minimum.

In the third step, yield ranges between maximum and minimum limits are derived on basis of the actual nutrient uptakes. Yields at maximum accumulation of nutrients in the crop (YNA, YPA, YKA) and at maximum dilution (YND, YPD, YKD) are calculated as the product of actual uptake (U) and physiological nutrient use efficiency (PhE) at accumulation and dilution (PhEA and PhED), respectively. PhE in this study is expressed in kg parchment coffee per kg of nutrient taken up.

The fourth step mainly followed the QUEFTS principles. Yield ranges are combined in pairs (YNP, YNK, YPN, YPK, YKN, and YKP) taking nutrient interactions into account. The average value of those six yields is considered the final yield estimate (YE). Some restrictions are imposed to ensure that calculated YE does not surpass the maximum dilution of N, P or K (YND, YPD YKD) or the maximum yield that can be obtained in view of climate and crop properties (YMAX). For coffee, the concepts of $Y_{tree}MAX$ and YMAX were introduced as maximum yield limits per tree and per ha, respectively.

Two additional steps were introduced to facilitate the assessment of the nutrient inputs required for a certain target yield [24]. Step 5 deals with the calculation of physiologically optimum nutrient proportions and the correspondingly required nutrient inputs for balanced crop nutrition. In Step 6 the economically optimum combinations of nutrient inputs are assessed as a function of target yield, soil available nutrients, and prices of input nutrients and yield.

2.3 Application of the model for coffee land evaluation

The new model was used to estimate yields on basis of spatial soil data from Hai and Lushoto districts. Data for OC, Total N, Bray 1 P, exchangeable K and pH were used. Those parameters whose units were percentage (OC and total N) and $cmol_c\ kg^{-1}$ (exchangeable K) had to be multiplied by ten to convert to $g\ kg^{-1}$ and $mmol_c\ kg^{-1}$ respectively. Plant density was set at 2000 trees per ha (spacing of 2.0 x 2.5 m^2). Other model parameters were left as default.

Data on baseline yield for the two districts were converted to shapefiles under ArcView GIS 3.2 (ESRI, 1996) and then interpolated under GRASS environment by using Quantum GIS Version 1.8.0 Lisboa. The inverse distance weighting (IDW) interpolator was used with number of nearest neighbours set to 12 and the power set to 2. Baseline yield data for the two districts [25] was used as a yardstick to test various human intervention strategies; farmyard manure used alone, at 5 tons per ha (about 2.5 kg per tree); inorganic fertilizer N, P and K at the dosage of 160, 60 and 160 kg ha-1; and a combination of the two. Scatter diagrams were used to show the effects of farmer ISFM practices in areas of low, medium and high natural fertility.

3. RESULTS AND DISCUSSION

3.1 The new model SAFERNAC

The calibration of QUEFTS for coffee gave rise to a new model SAFERNAC (Soil Analysis for Fertility Evaluation and Recommendation on Nutrient Application to Coffee). The model is built on Excel spreadsheet which allows for flexibility. Depending on the use to which it is put, it can follow one of the two separate approaches –baseline and ISFM. The parameters that differentiate the two approaches are based on Step 1. Figure 5.1 is a schematic representation of the model. The module PLANT comprises all indices related to the coffee crop (plant density, maximum yields per tree and per ha, PhEA and PhED). The module SOIL comprises five soil fertility indices (pH, organic carbon, total nitrogen, available phosphorus and exchangeable potassium), and the module INPUT comprises addition of organic and/or inorganic nutrient sources. In the spreadsheet the baseline approach is pursued by assigning zero values to all nutrient input columns. This approach simulates coffee yields under natural fertility, and is meant for use in coffee land evaluation. The ISFM approach assigns non-zero values to the nutrient input columns on spreadsheet, whereby the nutrients can be inorganic, organic or a combination of the two.

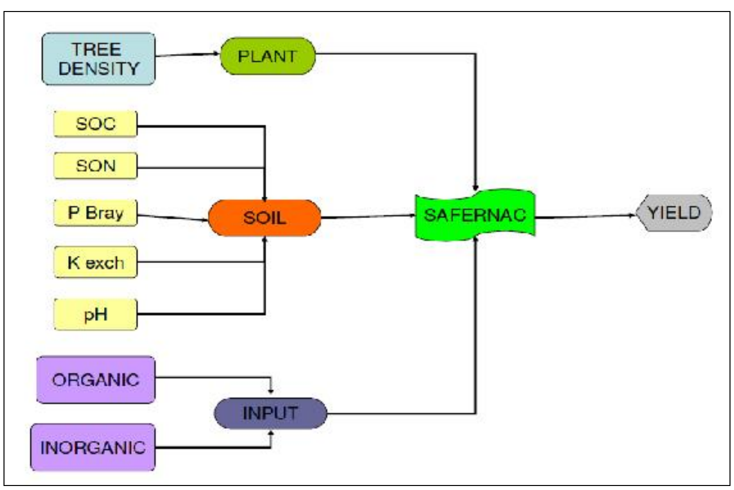

Figure 5.1: Complete structure of SAFERNAC. Baseline and ISFM approaches are separated by assigning zero and non-zero to the “input” columns on spreadsheet.

3.2 Model assumptions and prerequisites

The system operates under the following conditions, most of which affect Step 1 equations, with the other steps more generic:

- Soil fertility is conceived as the capacity of a soil to provide plants with nitrogen, phosphorus and potassium as primary macronutrients. The system assumes therefore that other nutrients are far less limiting than those three.
- Irradiance and moisture availability are optimum,
- Soil is well drained (minimum of drainage class 3 – [26]),
- Soil is deep enough (90 cm and more),
- pH(H_20) is in the range 4.5-7.0,
- Values for SOC, P-Bray 1 and exch K for the topsoil (0-20 cm) are below 70 g kg^{-1}, 30 mg kg^{-1} and 30 mmol kg^{-1}, respectively.

3.3 Calibration of model parameters of SAFERNAC

Results of model calibration are summarized in Appendix 1. These include a simplification of constants (as in fK, SAN, SAP and SAK), introduction of INPUT parameters IAi and IAo and an important PLANT parameter fD in Step 1. Another major adjustment is in Step 3, where the PhE values were recalibrated and expressed as kg parchment coffee per kg of nutrient taken up at accumulation “a” and dilution “d” as shown in Table 3. On the other hand, the factors rN, rP and rK subtracted from UN, UP and UK respectively for maize was removed – they do not apply in areas growing coffee in Tanzania. Step 4 follows QUEFTS principles. Additionally, limitations have been set to the model such that YE ≤ max (YND, YPD, YKD, YMAX) by using two PLANT parameters Y_{tree}MAX and YMAX.

Table 3: Physiological efficiency at maximum, medium and minimum availability of N, P and K (in kg parchment coffee)

	PhE	Symbol	N	P	K
Maximum	PhED	d	21	120	24
Medium	PhEM	m	14	80	16
Minimum	PhEA	a	7	40	8

3.4 Balanced NPK Nutrition and crop nutrient equivalents

Some principles of balanced NPK nutrition and crop nutrient equivalents as explained by [27] and applied in Rwanda [28] are adopted in this work. It is assumed that the values of uptake efficiency (UE = U/A) and those of physiological efficiency (PhE = Y/U), averaged for all three nutrients N, P and K, are maximum when the available amounts and the uptakes of N, P and K have optimum proportions. In case the ratio PhED/PhEA is the same for N, P and K, the optimum proportions are equal to the ratios of the reciprocals of the medium physiological efficiencies (PhEM). This implies that in a situation of balanced nutrition, 1 kg of available N has the same effect on coffee yield as 0.175 kg of available P, or 0.875 kg of available K, and similarly does the uptake of 1 kg N have the same effect on coffee yield as the uptake of 0.175 kg P or 0.875 kg K. These values are used to define the unit of nutrient equivalents, referred to as kE.

Once "target yield" or TY and PhEM are known, the relationship Y = U * PhEM can be used in determining the target uptake (TU) and target availability (TA), the latter being the sum of SA (available nutrients from the soil) and IA (available nutrients from input). When SA is known we can estimate the amount of nutrients needed to be added to the soil (both organic and inorganic) to attain the target yield: IA = TA-SA. For balanced crop nutrition, TAN = TAP = TAK, TAi being expressed in kE.

Balanced nutrition is the best possible situation from the environmental point of view, as it ensures maximum uptake of the available nutrients and minimum loss to the environment. Expressing quantities of nutrients in (k)E, and substituting $A_1 = A_2 = A_3$, $d_1 = d_2 = d_3$, $a_1 = a_2 = a_3$ and d/a = 3 in Step 3, it follows from that U/A = 0.9583. The average value of the uptake efficiencies is then maximum (being 0.96), and hence the average portion of non-utilized available nutrients is at minimum, being only 4%.

Because soil available nutrients are usually not in optimum proportions, nutrient inputs should be managed in such a way that the sums of (SA + IA) get balanced. This implies that inputs should start with the most limiting nutrient. It should be applied till the available amounts of the most and the one but most limiting nutrients are in balance. Further application should be with these two nutrients according to their optimum proportions till the supplies of all three nutrients are balanced. From there onwards, all three nutrients are applied according their optimum proportions. An example is given in Figure 2 representing an imaginary soil having organic C 26g kg^{-1}, organic N 2.6 g kg^{-1}, P-Bray-I 52 mg kg^{-1}, exchangeable K 20 mmol kg^{-1}, and pH(H_2O) 5.2. The amounts of soil available N, P and K are then 71.5, 30.4 and 295.4 if expressed in kg ha^{-1}, and 71.5, 173.8 and 337.6 if expressed in kE ha^{-1}. The sum of soil available nutrients is 583 kE ha^{-1}. Tree density is set at 2000 and hence fD is 0.76. The calculated yield without fertilizer application is 1086 kg ha^{-1}. Because SAN is smaller than SAP and SAK (expressed in kE), inputs should start with N, followed by N+P, and finally with N+P+K. The maximum possible yield is 3800 kg ha^{-1}. That is why in Figure 2 the yield curve levels off at high quantities of available nutrients.

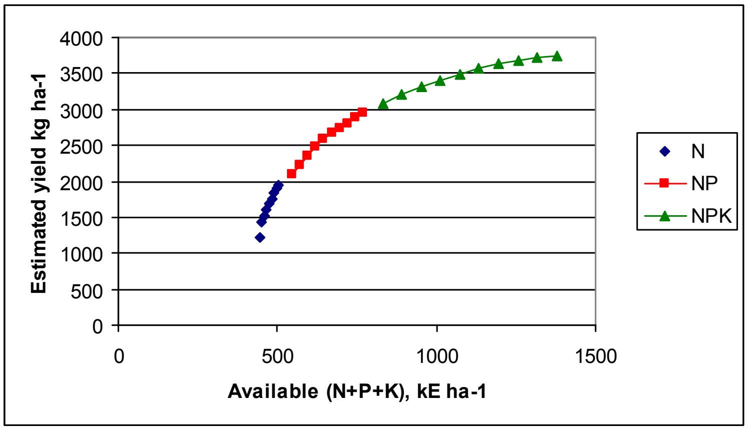

Figure 2: Relation between calculated coffee yields and the amount of available nutrients expressed in kE ha $^{-1}$, for three ranges of nutrient input.

3.5 Outcomes of model demonstration

In Appendix 2, the outcomes of the successive steps 1-4 in the basic SAFERNAC spreadsheet are shown as a two-treatment example for the on-station experiment of Usagara C: amounts of available nutrients (A), actual uptake (U) of N, P and K, yield ranges (Y_1A, Y_1D), yields as a function of nutrient pairs ($Y_{1,2}$ and $Y_{2,1}$) and the final yield estimate YE. U1,2 stands for UN(P), UP(K), UK(N); U1,3 for UN(K), UP(N), UK(P). Y1,1 stands for YNP, YPK, YKN; and Y2,1 stands for YPN, YKP, YNK. The model was run using the soil analytical data in Table 2 as starting points.

Figure 3 compares the yields simulated by SAFERNAC (YE) with actual yields (Y_{act}) for the NPK reference trial Usagara C and the fertilizer and tree density trial Lyamungu, of which soil data are given in Table 2. Actual yields were 80-100% of the simulated yields and the lines forced through the origin showed good R^2 values. The calibrated equations have therefore demonstrated their capability to reproduce the yields of the trials that had been used for their calibration to a satisfactory degree.

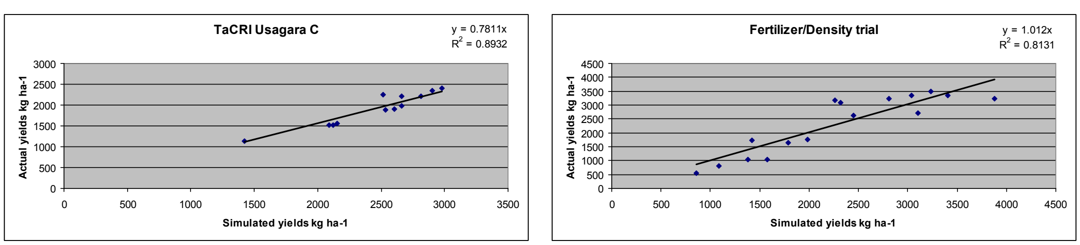

Figure 3: Simulated and actual parchment yields, TaCRI on-station trials

3.6 Estimated baseline yields Hai and Lushoto

Figure 4 shows baseline yield as estimated with SAFERNAC. The baseline yield map for Hai somewhat follows the soil fertility map, with higher yields to the east and north, and lower yields to the west. Yield seems to be influenced more by total N and OC than the other parameters. The yield map for Lushoto appears to contrast the soil fertility map, with the "fertile" areas to the east having lower yields than the "less fertile" areas to the west. The yield range is much narrower than the one for Hai (100-450 kg ha^{-1}). Higher yields were noted in the north (Mtae; 300-450 kg ha^{-1}) and in the south (Bumbuli, Soni and Mgwashi). Bumbuli is a traditional coffee grower with traditional coffee varieties N39 and KP423, while Mtae is an upcoming one with few farmers who are using the new improved coffee varieties.

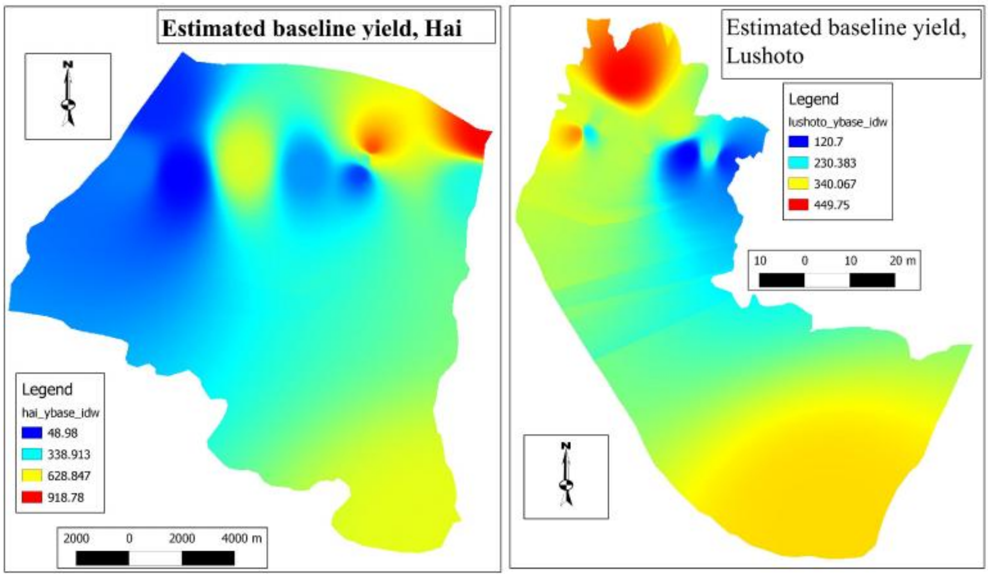

Figure 4: Baseline yield estimated with SAFERNAC, Hai and Lushoto districts

3.7 Evaluation of ISFM practices

Evaluation results for farmer practices are given in Table 4. The slope represents the rate of change in yield from ISFM interventions with the baseline yield; the latter taken as an indicator of soil fertility. These results are comparable to those of [29] when testing PARJIB model with maize in New Zealand. From the results it is noted that the effect of human intervention (with manure, fertilizer or both) tends to be felt more where baseline yield is low (the increasing Y-intercept), and diminishes progressively as baseline yield increases (the decreasing slope). In other words, response to fertilizer input is greater in soils of lower fertility and vice-versa, and that the uptake of a nutrient is higher in its dilution and lower in its accumulation. The noted variable R^2 values are an indication that the soils, even within districts, differ in soil fertility and therefore response to ISFM interventions.

Table 4: Summary of scatter-plot equations comparing ISFM interventions (manure, fertilizer and combination of the two) against baseline yields, both calculated with SAFERNAC.

District	**Hai**			**Lushoto**		
Parameter	**Y-int**	**Slope**	**R^2**	**Y-int**	**Slope**	**R^2**
Manure alone	**438**	**0.88**	**0.76**	**426**	**0.60**	**0.44**
Fertilizer alone	**1200**	**0.68**	**0.31**	**988**	**0.35**	**0.05**
Combination	**1500**	**0.66**	**0.22**	**1240**	**0.25**	**0.02**

3.8 Description of SAFERNAC in relation to major model categories

A model is a simplified representation of a system. A system is a limited part of reality that contains interrelated elements. The totality of relations within the system is the “system structure”. Simulation is the building of mathematical models and the study of their behaviour in reference to those of the systems [30]. Models may be categorized as descriptive or explanatory, empirical or mechanistic, static or dynamic depending on whether a component of time is included, deterministic or stochastic depending on the level of probability allowed; simulating and optimizing depending on intended use [30], [31]. SAFERNAC can be considered partly as a mechanistic model, partly as an empirical model. It is explanatory, but since it does not simulate changes in time it is not a dynamic model.

The major part of the model which is described in this paper (Steps 1-4), deals with simulation of (nutrient-limited) coffee yields, but as balanced nutrition and economically optimum applications of N, P and K are incorporated (Steps 5 and 6), SAFERNAC has optimizing properties as well. Like QUEFTS, it is meant as a useful tool in quantitative land evaluation and in decisions regarding integrated soil fertility management (ISFM). The yield predicted by SAFERNAC in its baseline module (with no nutrient inputs) can be used as an integrative indicator of soil fertility, which is one of the land qualities used in land evaluation. The principle of balanced NPK nutrition can be applied to arrive at target yields in the most profitable and environmentally friendly way.

3.9 Nutrient limited, water limited and potential yields of coffee

In many crop growth models, it is usual principle to distinguish between potential, water limited, nutrient limited and actual yields [11], [32]. SAFERNAC and QUEFTS simulate nutrient-limited yields, with the assumption that soil nutrient supplies in the agro-ecological zones that grow coffee in Tanzania would limit crop growth more severely than water availability (the determinant of water-limited yields –WPP), and certainly more than irradiance or temperature (which, together with the crop characteristics, govern the potential yield – RPP). It may be necessary in the future to include an agro-meteorological component (like the one suggested by [14]) as climate change becomes more and more important for coffee in the country.

So far SAFERNAC has been developed for a mono-crop of non-shaded coffee. This means that it is more useful in coffee estates (most of which prefer non-shaded coffee) than in smallholder farms. In shaded systems however, irradiance needs to be considered because it is known to be a growth-limiting factor. Integration of various levels of shade (and various intercropping regimes) could enrich the PLANT parameter in SAFERNAC. Once this is achieved, the model will expand its usability to smallholder coffee producers. Another option would be to incorporate (parts of) SAFERNAC into a general coffee growth simulation model in the similar way that QUEFTS was incorporated in TechnoGIN [33].

4. CONCLUSION

A new model called SAFERNAC (Soil Analysis for Fertility Evaluation and Recommendation for Nutrient Application to Coffee) has been developed by calibrating QUEFTS (Quantitative Evaluation of the Fertility of Tropical Soils) for coffee. The objective of the model is to assess coffee production as a function of natural soil fertility and nutrient inputs. It can follow two separate approaches, a baseline and an ISFM (Integrated Soil Fertility Management) approach.

The basic structure of the model is described, where some chemical soil characteristics (soil organic carbon (SOC) and/or soil organic nitrogen (SON), P-Bray 1, exchangeable K and pH (water)), nutrient inputs, and maximum yields per tree and per ha are model inputs and coffee yield is the model output. When used to predict yield of parchment coffee per ha from soil fertility alone without intervention, the model acts as a coffee land evaluation tool. Where intensification of coffee production, e.g. via adjustment of plant density, is deliberated, both natural soil fertility and input of nutrients in form of chemical fertilizer, organic nutrient sources or a combination of the two, play a role. Additional required model inputs are then quantity and quality of added nutrient sources and tree density. It is also possible to ask the model to assess the required nutrient additions for a certain target coffee yield, given tree density and the mentioned soil data. The model then becomes an ISFM decision support tool for coffee.

After calibration of model plant nutrient parameters on the basis of literature data and of model soil parameters using yields of on-station trials of TaCRI, the model was able to reproduce the trial yields on the basis of SOC, SON, P-Bray 1, exchangeable K, pH water, tree density and applied fertilizer NPK by 80-100%. Model usability for coffee land evaluation and ISFM intervention was tested with soils of Hai and Lushoto districts, Northern Tanzania, and proved to be a useful tool in both avenues. The next step will be to pre-test the model among selected smallholder coffee farmers and estates.

DEFINITIONS, ACRONYMS, ABBREVIATIONS

Acronym	Description / Long form
A	Availability (of a certain nutrient) for plant uptake
a	Short form of PhEA or PhEmin
d	Short form of PhED or PhEmax
FAO	Food and agricultural organization of the United Nations
I_i	Input of nutrients in inorganic nutrient sources
I_o	Input of nutrients in organic nutrient sources
IA	Available input nutrients
INPUT	Model component dealing with application of nutrients
ISFM	Integrated soil fertility management
K	Potassium (or potash fertilizer)
kE	Nutrient equivalent (same effect on yield as 1kg N)
MRF	Maximum recovery fraction
N	Nitrogen
(S)OC	(Soil) organic carbon
P	Phosphorus
PhE	Physiological (or internal utilization) efficiency

PhEA	Physiological efficiency at accumulation
PhED	Physiological efficiency at dilution
PhEM	Physiological efficiency at balanced nutrition
PLANT	Model component dealing with plant properties like density
QUEFTS	Quantitative evaluation of the fertility of Tropical Soils
r	Parameter describing minimum uptake required for yield (not used for coffee in Northern Tanzania)
RE	Relative effectiveness of nutrients in organic sources
RPP	Radiation-thermal Production Potential
SA	Amount of available nutrients from soil alone (natural fertility)
SAFERNAC	Soil analysis for fertility evaluation and recommendation on nutrient application to coffee
SOIL	Model component dealing with soil properties of interest
SV	Substitution value (same as RE)
TA	Target amount of available nutrients
TaCRI	Tanzania Coffee Research Institute
TU	Target uptake (for a target yield)
TY	Target yield
U	Uptake
WPP	Water-limited production potential
Y_{act}	Actual yields from experimental sites
YE	Yield estimated by the model
YKA	Yield associated with the uptake of potassium at accumulation
YKD	Yield associated with the uptake of potassium at dilution
Ymax	Maximum attainable yield under salient phenological set-up
YNA	Yield associated with the uptake of nitrogen at accumulation
YND	Yield associated with the uptake of nitrogen at dilution
YPA	Yield associated with the uptake of phosphorus at accumulation
YPD	Yield associated with the uptake of phosphorus at dilution

APPENDIX 1 SUMMARY RESULTS OF CALIBRATING QUEFTS TO COFFEE.

Model steps	**QUEFTS**	**SAFERNAC**
1	fN= 0.25 (pH-3) fP= 1-0.5 (pH-6)^2 fK=0.625 (3.4-0.4 pH)	ƒN = 0.25 * (pH – 3) ƒP = 1 - 0.5 * (pH - 6)^2 ƒK = 2 - 0.2 * pH
	SN=fN * 6.8 * SOC or fN*68* SON SP=fP* 0.35 * SOC+0.5 * P-Olsen SK= (fK * 400 * exch.K)/ (2+0.9*SOC)	SAN = ƒN * 5 * SOC or ƒN * 50 * SON SAP = ƒP* 0.25* SOC + 0.5* P-Bray-I SAK = ƒK * 400 * exch.K/SOC

	Not considered	IAN_i = MRFN * IN_i = 0.7 * IN_i IAP_i = MRFP * IP_i = 0.1 * IP_i IAK_i = MRFK * IK_i = 0.7 * IK_i
	Not considered	IAN_o = REN * MRFN * IN_o = 0.42 * IN_o IAP_o = REP * MRFP * IP_o = 0.087 * IP_o IAK_o = REK * MRFK * IK_o = 0.7 * IK_o
	Not considered	$fD = -0.06 (D/1000)^2 + 0.5 (D/1000)$ where D = number of trees per ha, and *f*D = 1 for D = 3333 ha^{-1}.
2	Refer QUEFTS papers	Adopted as in QUEFTS
3	YND = 70 * (UN-5) YNA = 30 * (UN-5) YPD = 600 * (UP-0.4) YPA = 200 * (UP-0.4) YKD = 120 * (UK-2) YKA = 30 * (UK-2)	$Y_1A = a_1 * U_1$ $Y_1D = d_1 * U_1$ (a and d referring to PhEA and PhED in kg parchment coffee per kg of nutrient taken up)
	Factor "r" subtracted from U in the equations of yields.	The "r" factor removed. Situations that $U \leq r$ are not applicable in coffee growing areas.
4	Refer QUEFTS papers	Adopted as in QUEFTS. Concepts of $Y_{tree}MAX$ and YMAX added: $Y_{tree}MAX$ = 2.2 – 0.15 X YMAX = 1000 * X * YtreeMAX where X is 0.001 times number of trees per ha. (YE should not exceed YND, YPD, YKD or YMAX).
5	Additional step, not in QUEFTS	AN:AP:AK = UN:UP:UK = 1/PhEMN : 1/PhEMP : 1/PhEMK = (1/14): (1/80): (1/16) or **1 : 0.175 : 0.875**
		1 kEN = 0.175*kEP =0.875*kEK Where kE = kilo nutrient equivalent per ha.
6	Additional step, not in QUEFTS	An economic loop that considers the

		quantities and prices of inputs and output for calculating the economic optimum nutrient application
