2	Rice Response to Phosphorus and Potassium in
3	Fluvisol of Second Order Lowland in a Guinea
4	Savanna Zone of Sub-Saharan Africa
5	
6	ABSTRACT
7 8 9 10 11	<b>Aims</b> : Poor management of P- and K-fertilizers can affect Nitrogen effect in rice grain yield and nutritional quality as the most limiting nutrient for rice production in second order lowland of Guinea savanna in West Africa. For development of best management strategy of N, P and K fertilizers in this agro-ecosystem, the response surface curve of rice to P- and K-fertilizer rates was assessed with the recommended rate of nitrogen.
12 13	<b>Study design</b> : An agronomic trial including eleven (11) treatments in three replications was laid out in a complete randomized blocks design.
14 15 16	<b>Place and duration of the study</b> : During three successive cropping cycles of rice in 2012, the study was conducted in M'be II valley of the Centre Cote d'Ivoire, a Guinea savanna zone.
17 18 19 20 21	<b>Methodology</b> : Three rates of P- $Ca(H_2PO_4)_2H_2O$ [30, 60 and 90 kgPha <sup>-1</sup> ] as well as three of K-KCI [25, 50 and 75kg Kha <sup>-1</sup> ] and their recommended rates (13kgPha <sup>-1</sup> and 25kgKha <sup>-1</sup> ) in the humid forest zone were the treatments. A total of 80kgNha <sup>-1</sup> (urea) was applied in three splits to each of the micro-plots except in the control including no fertilizer. The rice variety named NERICA L19 was transplanted.
22 23	<b>Results</b> : The results showed a synergism between K- fertilizations and N-nutrition of rice likewise for P-fertilizer which has limited effect on K-nutrition.
24 25 26 27	<b>Conclusion</b> : The rates of 10kgPha <sup>-1</sup> and 75kgKha <sup>-1</sup> were recommended for the production of high grain yield and nutritional quality of rice when applying 80kgNha <sup>-1</sup> . However, further assessments of K and N were suggested for sustaining rice production in the studied agro-ecology.
28	Keywords: Lowland rice, mineral nutrition, Fluvisol, phosphorus, potassium, synergism.
29	1-INTRODUCTION
30 31 32 33 34	In West Africa and especially in Cote d'Ivoire, there is increasing of rice ( <i>Oryza sativa</i> L) importance as population principal food (56kg/person/year) whereas, the supplying depend on foreign rice importation for about half of the annual local need which account for about 683 671 tons ([1],[2]). The gap observed in local production is due to the predominance of rainfed rice cultivation (80%) with an average low yield of 1 tha <sup>-1</sup> according to Audebert <i>et al.</i> [3]. Therefore,

the development of irrigated lowland rice with a higher potential yield [4] is required. For this purpose, the savanna zone extending over the 2/3 of the country [5] and including the most developed lowland [6] is an important potential ecology. However, the rice yield obtained in the lowlands in Cote d'Ivoire is still lower than the potential expected [2].

This reduction of yield was due to different constraints including the cultivars, the poor management of water and weed as well as the effect of other biotic constraints which are being resolved ([7], [8], [9]) unlikely for soil constraints.

42 In fact, only fertilizer recommendations including N, P and K were done for upland rice cultivation 43 and for lowlands in the humid forest zone of Cote d'Ivoire ([10],[11]). These recommendations 44 cannot be adopted in all the ecologies in the basis of site specific fertility management principle 45 [12]. Moreover, the existing hydrographic hierarchy of lowland agro-ecologies affects the soil 46 types and their physic-chemical properties according to the respective orders [13]. Therefore, a 47 specific fertilizer management is required for each of lowland order for rice production when 48 sound site specific nutrient management studies are limited to the Sahel plain agro-ecosystem in 49 West Africa [14].

50 Knowledge gap was reduced by Nwilene et al. [15] when recommending N-P-K fertilizer rates for 51 lowland rice in savanna zone of Sub-Sahara Africa. But, this ecology is subdivided into difference 52 class including Sudan savanna, Derived savanna and Guinea savanna which are requiring 53 specific management for rice production respectively [16]. In the Guinea savanna, morpho-54 pedological [17] and agro-pedological [18] characterizations showed the importance of nitrogen 55 and/or potassium fertilizations for rice cropping in different lowland orders in the centre of Cote 56 d'Ivoire (acid bed rock). Moreover, N-rate (about 80kgNha<sup>-1</sup>) was identified by Becker and 57 Johnson [19] for high production of lowland rice in Guinea savanna as similar in the forest zone. 58 Still little is known about rice nutrition in phosphorus-P, meanwhile, this nutrient has high 59 interactions with N and K [20] and account for a main component of the basal fertilizer when 60 combined with K and N. Thus, it is important to determine the optimum doses of these nutrients in 61 interaction with nitrogen for a rational fertilization in rice cultivation, especially in second order 62 lowland which is more extended in Sub-Saharan Africa and particularly, in the Guinea savanna 63 zone of Cote d'Ivoire.

In fact, the optimization of the best rate of 80kgNha<sup>-1</sup>[19] for rice cultivation in lowland could decrease with inappropriate application of P and K fertilizers due to unbalanced nutrient effects, reducing rice grain yield and quality. Indeed, there is interaction between N and P [21] as well as for N and K [22]. Therefore, we assume existing interaction between P and K with synergistic or antagonistic effect on N valorization by rice, affecting its yield and nutritional quality.

69 The actual study is initiated to explore rice response to the rates of P and K in second order 70 lowland of Guinea savanna zone in Côte d'Ivoire. The aim was to identify optimum rates of P and 71 K combined with the best rate of 80kgNha<sup>-1</sup> for the production of high yield and good nutritional 72 quality of rice.

### 73 2. MATERIAL AND METHODS

#### 74 **2-1 Site characteristics**

An on-farm trial was conducted in the irrigable valley of M'be II (8°06N, 6°00W, 180 m) as a semideveloped land in the centre of Cote d'Ivoire. The ecology is a Guinea savanna zone with a bimodal rainfall pattern. The average annual temperature and rainfall were 28°C and 1200 mm
respectively. A five years old fallow dominated by *Lersiahexandra* (Poaceae) and *Frimbristulis*spp (Poaceae) was preceding the experiment. The soil is a Fluvisol (Table 1) developed on
granito-gneiss bed rock.

81

# 82 Table 1. Chemical characteristics of soil in 0 – 20 cm depth

Characteristics	Values
pH <sub>water</sub>	5.5
C (gkg <sup>-1</sup> )	3.12
N (gkg⁻¹ )	0.31
P-total (mgkg <sup>-1</sup> )	365
Available-P (mgkg <sup>-1</sup> )	150
Ca (cmolkg <sup>-1</sup> )	3.05
Mg (cmolkg <sup>-1</sup> )	2.26

Na (cmolkg <sup>-1</sup> )	0.17
CEC (cmolkg <sup>-1</sup> )	20.2

83 84

## 85 2-2 Rice variety

A rice variety named NERICA L19 (New Rice for Africa Lowland 19) was used for the study. It is an interspecific cultivar breaded by crossing *O. glaberrima* and *O. sativa* from Africa and Asia respectively. Its cropping cycle is about 90 days with a yield potential of 7-8 tha<sup>-1</sup> in research station. This variety was released by Africa Rice Centre (ex-WARDA) and disseminated in 2008 belonging to the most popular cultivars for lowland agro-ecology.

### 91 2-3 Experiment lay out

An area of 1500 m<sup>2</sup> of bush fallow was cleaned before doing bounds and canals for water 92 93 management. Thirty three (33) micro-plots of 5 m × 3m in dimension were tilled manually. The treatments were composed of P-TSP (30, 60, and 90 kgha<sup>-1</sup>) and K-KCI (25, 50 and 75kgha<sup>-1</sup>) 94 and applied as basal fertilizer combined with 1/3 (27kgha<sup>-1</sup>) of 80kgNha<sup>-1</sup> (Urea). Recommended 95 rates of 13kgKha<sup>-1</sup> and 25kgKha<sup>-1</sup> were also applied as treatment in addition to a no-fertilizer 96 97 treatment as control in a randomized complete blocks design with three replications. The trial was 98 set for three cropping cycles (Trial 1, Trial 2 and Trial 3). After 21 days, seed line nursery of rice variety NERICA L19 was transplanted per 2 plants and spaced by 20 cm × 20 cm in row and 99 100 between rows. At rice tillering and panicle initiation stages, two splits of the 2/3 of N-fertilizer (80kgNha<sup>-1</sup>) were applied respectively after drainage to reduced N-loss. Ten days after 101

transplantation, about 5 cm of irrigation water was recommended until the rice maturity except
 during N-fertilizer application requiring drainage. Manual weeding was done at 45 days after
 transplantation and the harvest was done in 8m<sup>2</sup> at the maturity leaving two lines in the borders.

105

#### 106 **2-4 Data collection**

Before the experiment, a soil sample was done in 0 - 20 cm depth for each micro-plot (centre) 107 108 using augur. Hence, a composite sample of soil was taken in order to process the physicchemical characterization (particle size, pH<sub>water</sub>, C-organic, N-total, available-P, exchangeable 109 110 Calcium-Ca, magnesium-Mg, potassium-K and cation exchangeable capacity-CEC). The date of 50% of rice flowering was recorded per treatment for calculation of the physiological cvcle 111 112 duration. At rice maturity, the numbers of tillers (TILL) and panicles (PAN) were counted in a 113 square meter of each micro-plot. The plant height (HEIG) was also measured for each treatment. 114 After the harvest, the rice was threshed and the grains and straw were separately dried and 115 weighed. The moisture content of the grain was measured and the grain yield (GY) was 116 determined at a moisture content of 14%. But the straw yield (SY) was directly determined after 117 the weighing operation.

Samples of grain (100g) and straw (300 g) were collected for determining N, P and K exportation in the basis of their concentrations ([N], [P] and [K]) in the samples and the yield of the concerning treatment.

#### 121 **2-5 Laboratory analysis**

122 The composite soil sample was air-dried at room temperature and sieve (2mm) before it was 123 grounded. The pH water was determined in a soil/solution ratio of 1: 2.5 using glass electrode 124 [23]. Soil content in organic-C was determined by the method of Walkley and Black [24] and that 125 of Olsen and Sommers [25] for total and available phosphorus contents in soil. The exchangeable 126 cations (Ca, Mg and K) and the cation exchangeable capacity (CEC) were extracted by 127 ammonium acetate (pH= 7) before using atomic spectrometry (Ca and Mg) and flame 128 spectrometry (K) for reading the concentrations respectively. The total-N in soil was also 129 determined using Kjeldahl method [26].

130 The concentrations of N, P and K were determined in grain and straw using Kjeldahl and 131 mineralization method as described by Pinta [27] respectively.

#### 132 **2-6 Statistical analysis of data**

133 GenStat discovery, edition 4 was used to process analyze of variance (ANOVA) of the studied 134 parameters. Indices of mean classification were generated by XLSTAT. Pearson correlation 135 analysis was done between P-rate, the total concentrations of N, P and K in both grain and straw 136 using the package of SAS version 9. This software was also used for analysis of surface curve 137 response was done for P and K respectively as well as for their interaction. Critical error for all the 138 analysis was fixed at 5% ( $\alpha = .05$ ).

- 141

#### 142 **3. RESULTS**

#### 143 **3-1 Treatment effects on yield parameters**

144 Table 2 shows the mean values of plant height as well as the numbers of tiller and panicle per 145 square meter in each treatment. There is higher significant (p<.001) effect of treatment on the 146 plant height and number of panicles for the three cropping cycles respectively compared with that 147 of the number of tillers. The highest mean values of plant height are observed for the treatments 148 T4 (60P-25K), T5 (60P-50K) and T6 (60P-75K). Whereas, the treatments T3 (30P-75K), T6 (60P-149 75K) and T9 (90P-75K) did so for the numbers of tiller and panicle. The treatment T6 (60P-75K) 150 is likely to be the best according to rice vegetative growth parameters. However, there is a slight 151 decrease of the overall mean values of the studied parameters from the first to the last Trial.

#### 156 **3-2 Rice physiological cycle duration and yields**

157 According to the date of 50% of plant flowering, the duration of the physiological cycle was 158 recorded per treatment as well as for the grain and straw yields (Table 3). The effect of applied 159 treatments is highly significant (P<.001) on the studied parameters across the three trials. Highest grain yield (GY) of about 2.8 tha<sup>-1</sup> was recorded for the treatments T3, T6, and T9 and the highest 160 161 straw yield (SY) of about 5.2 tha<sup>-1</sup> is further observed for T3 and T6. But there is no significant difference between the mean values of the physiological cycle duration of the above treatments. 162 163 The overall mean value of yields is twice higher for SY than that of GY. Moreover, no significant 164 difference is observed between the grain yield mean values of across the three cropping cycles 165 (Figure 1) despite of 1 to 3% of reduction.

166

167 Figure 1: Rice grain yield mean values during the trials 1, 2 and 3.

#### 168 **3-4 Mineral concentrations in rice grain and straw**

Table 4 shows the mean values of N, P, and K concentrations in rice grain per treatment for respective cropping cycles. There is significant (P<.001) effect of the treatment in these parameters. The mean values of N and P concentrations are ranging from 1.49% to 0.18% respectively with the highest values for the treatments T3, T6 and T9 while the highest concentration of K (0.26%) is determined for the treatment T3.

197 G. Mean: Grand mean; a, b, c, d, e and f are indicating mean values with significant difference in column. There is also a significant effect of the treatments on the related mineral concentrations in rice straw (Table 5), and the highest concentrations are observed for treatments T3, T6 and T9 indifferently to cropping cycle.

#### Table 6: Pearson correlation coefficient (R) and probability (P) between P-rate and total concentrations of N, P and K in above ground biomass (grain and straw)

		P-rate	K	Ν	Ρ
P-rate	R	1			
	P> t				
К	R	0.53	1		
	P>  t	.09			
N	R	0.60	0.99	1	
	P> t	.04	<.0001		
Р	R	0.56	0.96	0.98	1
	P> t	.06	<.0001	<.0001	

203

P-rate is positively (0.60) and significantly (p =.04) correlated with the total N concentration in above ground dry matter contrasting with the result observed for P-rate and K concentration.
However, positive and significant correlations are also observed between K concentration and that of N (0.99) and P (0.96) respectively.

208

### 209 **3-5 Rice response curves to the rates of P and K**

Figure 2 shows rice response to the rates of P-fertilizer. A polygonal trend is observed showing a response of rice grain yield early at 10kgPha<sup>-1</sup>. The increase of P-rates further induces a slight increasing of grain yield up to 2tha<sup>-1</sup> corresponding to the rate of 47.50kgPha<sup>-1</sup>. Further application of P-fertilizer provokes yield declining up to the rate of 90kgPha<sup>-1</sup>.

216 Figure 2: Rice grain yield (GY) response curve to P-rates.

217

218 Figure 3: Rice grain yield (GY) response curve to K-rates.

Figure 3 shows a low response of rice grain yield (<1.75 tha<sup>-1</sup>) to K-rates ranging from 0 to 20kgha<sup>-1</sup>. Thereafter, an increasing of rice response to  $\frac{1}{K}$ -rates is observed as illustrated by a linear trend of grain yield according to the increase of the fertilizer application up to 75kgKha<sup>-1</sup> for a grain yield of 3tha<sup>-1</sup>.

- 223 The characteristics of rice response to the combination of different rates of P- and K-fertilizers are
- 224 presented in Table 7 and Figure 4. There is a significant (P<.0001) linear trend with R<sup>2</sup> = .94 of
- rice response whereas, these parameters are minimized for the quadratic trend (P=.04; R<sup>2</sup>=.037) 225
- according to Table 7. In addition to the information recorded in Figures 2 and 3, rice response is 226
- 227 likely to be more depending to K-fertilizer when combine with that of P according to Figure 4.

Regression	DF	SSM	R <sup>2</sup>	Pr> F				
Linear	2	1.611	0.9402	< .0001				
Quadratic	2	0.063	0.0372	.0406				
Cross Produce	1	0.014	0.0083	.1481				
Total model	5	1.689	0.9857	.0001				
Optimum rate of P (tha <sup>-1</sup> ) 47.27								
Optimum rate of K (tha <sup>-1</sup> ) 74.99

230

#### 234 4. DISCUSSION

#### 235 4-1 Quantitative and qualitative improvement of rice by potassium

The soil of the studied site has a low content of K (0.08 cmolkg<sup>-1</sup>) with a K/CEC ratio of less than 236 3% confirming this nutrient deficiency. This assertion is further supported by the response of rice 237 vield to the rates of K as observed from 10kgKha<sup>-1</sup> with an increasing linear trend up to 75kgKha<sup>-1</sup> 238 <sup>1</sup>. Therefore, the recommended rate of 25kgKha<sup>-1</sup> by Sanogo *et al.* [11] for humid forest ecology is 239 not suitable for the studied agro-ecology. In fact, this recommendation will induce about 2tha<sup>-1</sup> as 240 grain yield while it was possible to observed 3tha<sup>-1</sup> by applying 75kgKha<sup>-1</sup> according to our results 241 (Figure 3). However, there is a need to explore the net benefit of such yield gap according to 242 243 fertilizer strategy [28]. Anyway, these analyses justified our assumption of site fertility 244 management [12] requirement for K-fertilization strategy improvement in lowland rice cultivation. 245 In fact, previous knowledge is related to the humid forest zone while our study was conducted in 246 a Guinea savanna zone. In other hand, our finding corroborate with the results of Konan [18] 247 concerning K-deficiency for rice cultivation in the studied agro-ecology emphasizing the increase 248 of N concentration in the grain for the highest rate of K (75kgKha<sup>-1</sup>). This aspect revealed high 249 translocation of N into the grain depending in K-fertilizer supplying attesting a synergistic relation 250 between both nutrients as mentioned by Slaton et al. [22]. A good water management is required 251 to reduce leaching and denitrification process of N in order to enhance nitrogen use efficiency 252 across seasons (dry and wet) [29]. As nitrogen is essential for protein synthesis ([30],[31]), we 253 deducted that K-fertilization can improve rice grain nutritional quality particularly since this synergism also occurred for P and K (Table 6). 254

Therefore, our study pointed out quantitative and qualitative improvement of rice production in second order lowland in Guinea savanna depending in K-fertilization.

#### 257 4-2 Limited and mitigated effect of phosphorus

The studied soil content (150 mgkg<sup>-1</sup>) of available-P as determined by Olsen method was ten 258 times higher than the critical level [32]. However, there was a response of rice to applied P-rates 259 as observed significantly for the numbers of tiller and panicle (Table 2) as well as for the grain 260 yield. The grain yield response was observed from the rate of 10kgPha<sup>-1</sup> which induced vield 261 increasing by 0.3tha<sup>-1</sup> compared with that (1.5tha<sup>-1</sup>) of the control treatment (T0). Further 262 increasing of P-rate up to 45kgPha<sup>-1</sup> has induced slight increasing of the grain yield to a 263 maximum of 2tha<sup>-1</sup> thereafter; the grain yield declined for additional application of P-rates. This 264 265 result is further contrasting with the studied done by Konan [18] in the same ecology. But the quadratic trends of rice grain and straw yields according to P-rates as observed in the actual 266 study can explain the low yield obtained by this author when applying 60kgPha<sup>-1</sup>. In fact, the 267 yields were significantly reduced from 45kgPha<sup>-1</sup> to 90kgPha<sup>-1</sup> (Table 3). However, similar 268 contrast of rice response to P was also observed with 916mgPkg<sup>-1</sup> (Olsen) in a soil during the 269 270 work done by Singh et al. [33] as consequence of negative balance of soil P content across 271 successive cropping whereas, this response occurred early during the first cropping cycle of the 272 actual study. It is likely that P-deficiency has occurred ongoing cropping similarly to the assertion 273 of Alva, Larsen and Bille [34]: P-immobilization results to oxygen secretion by rice roots under 274 submersion. Moreover, reversibility of P as resistant P-Ca can occurred because of the nature of 275 the bed rock of the studied soil [35]. However, increasing P availability was also observed by 276 Jones et al. [36] under flooding condition.

- Definitively, we assert that rice response to 10kgPha<sup>-1</sup> can be observed even in a soil with 150kgPkg<sup>-1</sup> (Olsen) as result of P-immobilization with mitigated effect which is limited at 45kgPha<sup>-1</sup> <sup>1</sup> in the studied agro-ecosystem. Consequently, the increase of P-rate throughout the treatments T3, T6 and T9 did not induce significant difference between the concentrations of N, P and K in the grain and straw respectively. However, total N concentration in above ground dry matter was positively and significantly correlated to P-rate (Table 6). The calcium contained in phosphate fertilizer can contribute to this as synergism effect with described by Saijo et al. [37].
- Therefore, in spite of the limited effect of P-rates on rice yield, it is likely to increase rice grain nutritional quality in relation to N uptake when increasing supplied P. In turn, P and K uptake were not concerned as much contrasting with the role of P-nutrition in the active transport of nutrients in plants [38].
- In the basis of these analyses, there is a need of further investigations of rice P-nutrition in
   irrigated lowland where the submersion can confers some particularities to the soil properties [39]
   compared with the upland ecology.

### 291 **4-3 Sustainability of rice production**

- The treatments T3, T6 and T9 including 30, 60 and 90kgPha<sup>-1</sup> respectively which was combined 292 293 with constant rates of N (80kgha<sup>-1</sup>) and K (75kgha<sup>-1</sup>) have induced the highest grain yields with shorter physiological cycles (Table 3) and contrasting with the recommended rates for lowland 294 rice cultivation in the humid forest zone [11]. Unarguably, the rates of 80kgNha<sup>-1</sup>, 30kgPha<sup>-1</sup> and 295 75kgKha<sup>-1</sup> can be recommended for rice production in the studied agro-ecology. However, the 296 yield observed for the rate of 10kgPha<sup>-1</sup> in Figure 2 did not differed significantly with that of 297 298 30kgPha<sup>-1</sup> allowing change in fertilizer recommendation for rice cultivation in second order 299 lowland of Guinea savanna zone for economical reasons that can influence the adoption of 300 fertilizer recommendation [40].
- 301 There is also a possibility to increase the rice grain yield by further increase of K-fertilizer rate in the basis of the linear trend observed for the grain yield (Figures 3 and 4). Indeed, the increase of 302 K-rate is necessary because of the exportation of about 61.20 kgKha<sup>-1</sup> per cropping cycle and the 303 304 low (<0.10 cmolkg<sup>-1</sup>) K content in the soil. In fact, a best fertilizer management might be able to 305 restore the fertility of the soil and supply the crop need of nutrients [41]. In this basis, the rate of 75kgKha<sup>-1</sup> may be insufficient regarding to the yield reduction across the successive cropping 306 307 cycles although not significant during the experiment, such trend of yields can impairs the 308 sustainability of rice production in lowland as far as. Thus, we suggest the increase of applying rate of K over 75kgKha<sup>-1</sup> and to assess rice response to N in order to determine their optimum 309 doses during further study in the way of sustaining rice production in second order lowland of the 310 311 Guinea savanna zone in Sub-Saharan Africa. In fact, the high production of rice as indentify for about 80kgNha<sup>-1</sup> by Becker and Johnson [19] was not specific to lowland orders. Nutrient 312 313 management tool as QUEFTS model ([42]:[43]) should be use considering particularly season 314 effect as it can be induced in different locations.

### 315 5. CONCLUSION

Our study revealed an optimization of rice nutrition in nitrogen due to potassium and phosphorus fertilizations on Fluvisols as induce by a synergism effect, resulting quantitative and qualitative improvement of rice production. It is recommended the application of 10kgPha<sup>-1</sup> and 75kgKha<sup>-1</sup>

- for quantitative and qualitative rice production in irrigated second order lowland of Guinea savanna which is different with the previous recommended fertilizer practice in the forest zone.
- However, for improving the sustainability of rice production, it is suggested to deepen knowledge of rice nutrition in phosphorus and to reassess K-rates in the studied agro-ecosystem using
- 323 model and emphasizing site and season effects when specific rate of N should be identified.
