This study was undertaken to determine the comparative effects of cobalt (II, III) oxide  $(Co_3O_4)$  macro- and nano-particles, and cobaltous chloride hexahydrate  $(CoCl_2.6H_2O)$  on seed germination, growth and some biochemical parameters of *Hordeum vulgare* L. seedlings. Macro- and nano-Co was added to the sand medium at four levels (50 to 200 mg kg<sup>-1</sup> sand). Macro-Co was found to increase the growth of both shoots and roots at concentrations up to 200 mg Co kg<sup>-1</sup> sand. Increase in concentration of nano-Co decreased the root length. Lipid peroxidation was maximum at 200 mg Co kg<sup>-1</sup> sand for macro-Co in roots. Increase in the lipid peroxidation was found in nano-Co treated roots and shoots. Nano- and macro-Co<sub>3</sub>O<sub>4</sub> behaved differently with respect to effects on barley seedlings. The present study also demonstrated the ameliorative effect of NaOCI against CoCl<sub>2</sub>.6H<sub>2</sub>O toxicity in barley seedlings. NaOCI also decreased the lipid peroxidation induced by CoCl<sub>2</sub>.6H<sub>2</sub>O and increased chlorophyll content in seedlings.

## 17 1. INTRODUCTION

18

19 Fast pace of industrialization and irrational use of natural resources have led to metal 20 accumulation in the environment. Metal accumulation in soil is of great concern in agriculture 21 due to its adverse effects on food safety and marketability, plant growth, and soil microflora 22 and fauna [1]. Metal toxicity has high impact on the plants which consequently affect the 23 whole ecosystem due to interdependence of living organisms. Cobalt (Co) is a transition metal with atomic number 27 and atomic weight 58.9 g mol<sup>-1</sup>. The role of Co in nutrition of 24 25 leguminous plants is well known, but its importance to the rest of the plant species is still 26 ambiguous [2]. It is an essential element for the synthesis of various enzymes and 27 coenzymes like vitamin  $B_{12}$  (cyanocobalamin), which are required for human and animal 28 nutrition. Co is safer for consumption up to 2.5 - 3.0 mg daily, without any adverse health 29 effects [3]. It acts as a coenzyme in a number of cellular processes including the oxidation of 30 fatty acids and the synthesis of DNA. Toxic concentrations of Co inhibit active transport in plants. Relatively higher concentrations of Co have toxic effects, including leaf fall, inhibition
 of greening, discolored veins, premature leaf closure and reduced shoot weight [4].

Two salts of Co are used in industry on a large scale, Co (II, III) oxide, also known as CoO.Co<sub>2</sub>O<sub>3</sub> or Co<sub>3</sub>O<sub>4</sub>, macro- and nano-scale particles which are insoluble in water; and cobalt chloride (CoCl<sub>2</sub>.6H<sub>2</sub>O, macroscale particles, water soluble). Nano-Co<sub>3</sub>O<sub>4</sub> is a recent discovery and needs to be investigated in detail. CoCl<sub>2</sub>.6H<sub>2</sub>O is toxic at higher concentrations.

38 Nanotechnology is the engineered convergence of biology, chemistry and informatics at 39 nanoscale. The products of these exertions are called nanomaterials, consisting of 40 nanoparticles (NPs), having a size smaller than 100 nm in at least one dimension. Among 41 the latest technological innovations, nanotechnology possesses the top position [5]. The 42 properties of nanomaterials raise concern about their potential adverse effects on biological 43 systems at cellular level. Because of their small size, NPs get incursion into the living cell 44 membrane. In contrast to the classical macroscale particles, due to their smaller size and 45 huge surface area, NPs may interact more expeditiously with biological systems. Metal 46 oxide-based NPs are increasingly used in applications such as opacifiers, fillers, catalysts, 47 semiconductors, cosmetics, microelectronics etc. [6]. Therefore, interaction between 48 inorganic nanoparticles and biological systems is one of the most promising areas of 49 research in modern nanoscience and technology.

50 The present work is aimed at studying the differential effects of macro- and nano-particles of 51  $Co_3O_4$  and  $CoCl_2.6H_2O$  in combination with sodium hypochlorite (NaOCl) on barley 52 seedlings in sand medium. CoCl<sub>2</sub>.6H<sub>2</sub>O helps in color change in glass industry, organic 53 synthesis and electroplating objects, production of pigments in ceramics and as a mordant in 54 dry cleaners. CoCl<sub>2</sub>.6H<sub>2</sub>O is a catalyst used for metal surface treatment also. The waste from these industries contains Co more than the prescribed limit. Such industrial effluents when 55 56 reaching the crop fields cause toxicity to plants [7]. So, to remediate Co rich soil we have 57 tried to use sodium hypochlorite (NaOCI) for detoxification. NaOCI converts transition metal complexes into their oxides [8]. NaOCI is used in the pesticide and textile industries, and is a 58 59 disinfectant, cleaner and bleach.

## 60 2. MATERIALS AND METHODS

61 **2.1. Study material** 

63 Certified and disease-free seeds of barley (*Hordeum vulgare* L.) variety PL-426 were 64 purchased from Punjab Agricultural University, Ludhiana (India). Barley is generally grown 65 as a summer crop in temperate areas and winter crop in tropical areas (including India). It is 66 an important cereal of India, ranking next to wheat, maize and rice in the world.

67

## 68 2.2. Macro- and nano-Co<sub>3</sub>O<sub>4</sub> treatments

69

Salts of Co and other chemicals used in the study were purchased from Sigma-Aldrich, Banglore, India; HIMEDIA Laboratory Pvt Ltd; Loba Chemie Pvt Ltd and BTL Research Lab. Suspensions of both macro- and nano- $Co_3O_4$  were made in distilled water. Different concentrations of both macro- and nano- $Co_3O_4$  containing 0, 50, 100, 150 and 200 mg Co kg<sup>-1</sup> sand were prepared respectively.

75

## 76 2.3. CoCl<sub>2</sub>.6H<sub>2</sub>O and NaOCI treatments

77

Seeds of barley were grown in sand containing various binary combinations of CoCl<sub>2</sub>.6H<sub>2</sub>O
and NaOCI (Table 1). Growth and biochemical parameters were studied for any modulation
in CoCl<sub>2</sub>.6H<sub>2</sub>O toxicity to seedlings.

81

#### 82 2.4. Sand cultures and plant material raising

83

84 Seeds of H. vulgare were surface sterilized with 0.01% HgCl<sub>2</sub> and then washed under 85 running tap water for 10 min. After that, the seeds were soaked in distilled water for 1 h for 86 imbibition. Sand was filtered through sieve of 300 nm size, washed with 0.1 N HCl and thrice with deionised water, and was dried on filter paper in the oven at 80 - 85 °C for 3 days. The 87 88 imbibed seeds were then sown in polypropylene plastic jars of diameter 11 cm containing 0.5 kg sand supplemented with different concentrations of Co. In each jar, 30 seeds of 89 90 nearly the same size were sown. These sand cultures were maintained at a temperature of 91  $25 \pm 0.5^{\circ}$ C, 70 – 80 % relative humidity and 16:8 hour dark : light photoperiod (1700 lux). Then, different plant parts (shoots, roots) were harvested after 7 days of growth for the 92 93 estimation of root length (RL) and shoot length (SL), fresh weight (fw) and dry weight (dw). 94 Biochemical parameters were studied in terms of oxidative stress caused by metal salts. 95 These included lipid peroxidation and estimation of chlorophyll content. Malondialdehyde 96 (MDA) was estimated according to Heath and Packer [9], and chlorophyll content was 97 measured by the method described by Arnon [10].

## 99 2.5. Statistical analysis

100

101 The experimental data were expressed as mean ± SE. One-way and two-way analysis of 102 variance (ANOVA) were done to check the significance of differences within and between 103 treatments, and interactions if any. Significance levels of F-ratios were checked at P = 0.05. 104 Honestly significant differences (HSD) were calculated using Tukey's multiple comparison 105 test at P = 0.05. Difference between any two means in ANOVA if larger than the HSD value 106 reveals a statistically significant difference. Linear regression and multiple linear regression 107 with interaction analyses were carried out in MS-Excel using self-coded software. 108 Pearsonian correlation and multiple correlation analyses were done to determine the 109 significance of correlativity among the variables. Unitless beta ( $\beta$ ) regression coefficients in multiple regression analysis were calculated in order to measure the relative effects of 110 111 independent variables (Co, NaOCI and CoxNaOCI interaction) on the dependent variable 112 [11].

114 **3. RESULTS** 

115

113

116 3.1. Growth cha	racteristics
---------------------	--------------

117

#### 118 3.1.1. Co<sub>3</sub>O<sub>4</sub> macro- and nano-particles treatment

119

Seedlings cultured in sand medium containing  $Co_3O_4$  (macro) showed increase in root and shoot length with increase in Co concentration (50, 100, 150 and 200 mg kg<sup>-1</sup>). Further it was observed that treatment of  $Co_3O_4$  nano-particles significantly increased shoot length but decreased root length (Table 2).

124

125 3.1.2. CoCl<sub>2</sub>.6H<sub>2</sub>O treatments in binary combinations with NaOCl

126

127 A significant decrease in shoot, root length and fresh weight (fw) dry weight (dw) of H. 128 vulgare was observed upon addition of various concentrations (250, 500, 750 and 1000 mg kg<sup>-1</sup>) of Co as CoCl<sub>2</sub>.6H<sub>2</sub>O. Further the role of NaOCI as a potent inhibitor of CoCl<sub>2</sub>.6H<sub>2</sub>O is 129 elucidated in Tables 3, 4 and 5. 750 mg kg<sup>-1</sup> of NaOCI concentration increased shoot length 130 of seedlings grown in 1000 mg kg<sup>-1</sup> Co amended sand by 58.57 % and root length by 86.67 131 %. 500 mg kg<sup>-1</sup> of NaOCI increased shoot fresh weight of 1000 mg kg<sup>-1</sup> Co treated seedlings 132 by 91.5 %. Two-way ANOVA variance ratio (F) describes the statistically significant 133 difference among shoot and root lengths on CoCl<sub>2</sub>.6H<sub>2</sub>O and the NaOCI treatments. Multiple 134

regression models showed that Co has negative effect on shoot and root length, while
NaOCI has a positive effect. Interaction between Co and NaOCI was found to be statistically
significant. Fresh and dry weight of shoots also showed significant differences (Table 6).

138

#### 139 3.2. Lipid peroxidation

140

141 Variations in shoot and root MDA content of H. vulgare grown in sand media containing 142 Co<sub>3</sub>O<sub>4</sub> macro- and nano-particles are presented in Table 7. The MDA content of H. vulgare 143 treated with macro-Co<sub>3</sub>O<sub>4</sub> was increased significantly for shoots, while a decreasing trend 144 was found in roots. The MDA content for both shoots and roots showed an increasing trend with increase in concentration (50, 100, 150 and 200 mg kg<sup>-1</sup>) of Co<sub>3</sub>O<sub>4</sub> nano-particles in a 145 146 dose dependent manner. The lowest value for MDA (shoots and roots) was found at concentration of 50 mg Co kg<sup>-1</sup> sand, while other concentrations showed increased amount 147 of lipid peroxidation. 750 mg kg<sup>-1</sup> of NaOCI decreased lipid peroxidation in 1000 mg kg<sup>-1</sup> Co-148 149 treated shoots and roots up to 10.65% and 14.63% respectively. One-way ANOVA showed 150 significant increase in MDA content in both roots and shoots treated with macro- and nano-151 Co. Two-way ANOVA revealed that there are significant differences among MDA contents of 152 both shoots and roots in binary treatments (Table 8). The interaction between Co and NaOCI 153 was found to be negative for both shoots and roots (Table 9).

154

### 155 3.3. Chlorophyll estimation

156 The effects of Co<sub>3</sub>O<sub>4</sub> macro- and nano-particles, and binary combinations of CoCl<sub>2</sub>.6H<sub>2</sub>O 157 with NaOCI on chl content (chl 'a', chl 'b' and total chl) are presented in Tables 10, 11. 158 ANOVA depicted statistical significant differences among different treatments on, chl 'b' and 159 total chl. Multiple regression analysis showed positive effect of NaOCI on chl 'a', which as a 160 result compensated the negative effect of CoCl<sub>2</sub>.6H<sub>2</sub>O. Co and NaOCl significantly increased 161 the chl 'b' content, whereas in the case of total chl, Co showed negative, while NaOCI showed positive β- regression coefficient. It was found that chl 'a', chl 'b' and total chl 162 showed maximum values at 200 mg kg<sup>-1</sup>. Significant increase was found in the chl 'a', chl 'b' 163 164 and total chl contents with increase in concentration of Co3O4 nano-particles in sand 165 medium. Such results depicted that nano-Co modulated chlorophyll synthesis. 500 mg kg<sup>-1</sup> of NaOCI concentration increased chl 'a', chl 'b' and total chl contents of 1000 mg kg<sup>-1</sup> Co-166 167 treated leaves by 76.06 %, 79.35 % and 77.81 % respectively.

#### 238 4. DISCUSSION

239

Heavy metals may cause major occupational and environmental hazards due to their non-biodegradable nature and long biological half life period [12]. Exposure to heavy metals is mainly due to the anthropogenic actions such as use of fertilizers, agrochemical compounds, sewage sludge and other activities like mining [13]. Such activities result in the transportation of metal ions via air and water, which ultimately bind to soil and sediments. Co is a relatively rare magnetic element with properties similar to those of iron and nickel, and occurs in nature primarily as arsenides, oxides and sulphides. Most of the production of Co involves the metallic form used in the formation of Co superalloys [14]. The distribution of Co in plants is entirely species specific.

247

A significant increase in both root and shoot length was observed in 7 days old seedlings treated with Co<sub>3</sub>O<sub>4</sub> macro-248 particles, while treatment of  $Co_3O_4$  nano-particles increased only shoot length. These observations are in accordance with 249 earlier studies [15] where cobalt is said to increase the seedling growth by alleviating the senescence of aged tissue by 250 inhibiting the activity of 1-aminocyclopropane-1-carboxylate (ACC) oxidase, and reducing ethylene production. 251 252 CoCl<sub>2</sub>.6H<sub>2</sub>O was found to be toxic at higher concentrations as was observed from decreased root and shoot length. 253 NaOCI decreased CoCl<sub>2</sub>.6H<sub>2</sub>O and induced decrease in both root and shoot length. NaOCI is known to transform Co into its oxide form either through exclusion, inclusion (i.e. sequestration and compartmentalization of metal ions in organelles) 254 or chelation binding [16]. The reaction of CoCl<sub>2</sub>.6H<sub>2</sub>O with NaOCI is given below: 255

$$3\text{CoCl}_2.6\text{H}_2\text{O} + 6\text{NaOCl} \xrightarrow{\text{Aqueous}} \text{Co}_3\text{O}_4 \text{ (ppt)} + 6\text{NaCl} + 3\text{Cl}_2 + 4\text{O}_2$$

257

The reason for such an observation might be attributed to the fact that NaOCI oxidises the more toxic  $CoCI_2.6H_2O$  to the less toxic  $Co_3O_4$  [8]. At treatments where NaOCI was absent altogether, metal-caused toxicity resulted in reduction of shoot length. Lowest shoot length was observed at concentrations where Co is in maximum and NaOCI is in minimum amounts. The amount of NaOCI required for counteracting toxicity caused by Co is more in the case of roots as compared to shoots. This may be attributed to the fact that roots are accumulative organs of heavy metals [17].

263

Lipid peroxidation was found to be maximum for roots at a concentration of 200 mg kg<sup>-1</sup> of  $Co_3O_4$ . The reason for such a trend can be attributed to increased production of ROS which induce membrane destabilization resulting in the formation of peroxides, as was reported by Mead et al. [18]. On the other hand,  $Co_3O_4$  inhibited lipid peroxidation by decreasing the MDA content in roots and the differences obtained were statistically significant.

268

A significant reduction in chlorophyll content (chl 'a', chl 'b' and total chl) induced by CoCl<sub>2</sub>.6H<sub>2</sub>O as compared to the untreated control might be due to overproduction of reactive oxygen species, which in turn could have damaged chloroplast membrane [19] as was observed on the effect of Co on *Cajanus cajan* Mill. Application of NaOCl in combination with CoCl<sub>2</sub>.6H<sub>2</sub>O increased levels of chl 'a', chl 'b' and total chl. Protection extended by NaOCl was evident from the fact that it significantly reduced ROS production as was observed in lipid peroxidation studies.

#### 277 **5. CONCLUSION**

278

Our results showed that Co<sub>3</sub>O<sub>4</sub>, both nano- as well as macro-particles showed differential toxic effects on *H. vulgare* seedlings. Furthermore, the application of NaOCI significantly reduced the toxicity caused by CoCl<sub>2</sub>.6H<sub>2</sub>O in *H. vulgare* seedlings. Improved Co stress mitigation by NaOCI involves biochemical ramifications. Thus, the present study presents NaOCI as effective candidate in ameliorating CoCl<sub>2</sub>.6H<sub>2</sub>O toxicity.
