Subject: RE: Request for final decision for manuscript number 2014\_IJTDH\_8945

I need to provide my feedback to you regarding this manuscript on "Nocturnal enuresis..." immediately for so many reasons.

1. The statistical computations presented by the authors are all inappropriate. Many of the cells in their cross-classifications have less than five, therefore they should use just frequencies. Even in their inappropriate use of Chi-square, they did not present their degree of freedom in their results.
2. The acronym ICCS should be clearly explained in their introduction not delay such explanation to page 8
3. There are several typographical errors
4. Under data analysis, they have treated and used data as singular verb instead of plural.
5. They claimed to use t-test to test for the relationship between continuous variables. This is plainly lack of knowledge. You use T-test to test for statistically significant differences between dependent and independent variables. Analysis of variance is an extension of T-test
6. The incipient onset of enuresis and the genetic precursors are associated with the epigenome and epigenetic environment of children.
7. Mothers who used alcohol, fed on pica, such as clay, smoked during pregnancy and used hard drug during pregnancy expose their children to enuresis

As currently written, this manuscript requires comprehensive revision and the authors must seek the assistance of a statistician and clinical epidemiologist.
